1417 THE DEVELOPMENT OF CHICK-EMBRYO-LETHAL-ORPHAN (CELO) VIRUS T AND V ANTIGENS IN LYTICALLY INFECTED CHICK KIDNEY CELLS. (E.) Anderson, J. (Baylor Coll Med., Houston, Texas), K. J. McCormick, W. A. Stenback and J. J. Trentin. *Int J Cancer* 7(1):59-64, 1971.

To determine the sequence of synthesis of tumor and virion antigens of chick-embryo-lethal-orphan (CELO) virus in lytically infected chick kidney cells, cultures were infected at 30 egg lethal doses (ELD₅₀). The antigens had been distinguished by their staining patterns; the tumor antigen was confined to the nucleus of infected cells and was morphologically similar to the SV40 tumor antigen; the virion antigen first appeared in the nucleus and then spread to cytoplasm. In lytically infected chick kidney cells, the indirect immunofluorescence test showed that tumor antigen developed 6 hr after infection and reached a peak of 90% antigen-positive nuclei at 20-24 hr postinfection. The virion antigen was detected 20 hr postinfection. The synthesis of both antigens was inhibited by cycloheximide, but only the virion antigen was inhibited by cytosine arabinoside. Tumor antigen in fixed cells could not be detected after storage for 3 wk in liquid nitrogen.

1418 A VIRUS OF HUMAN LEUKOSIS. (Rus.)

Barinskiy, I. F. (D. I. Ivanovskiy Inst. Virol., Moscow, U.S.S.R.), A. K. Shubladze, A. F. Bocharov, F. P. Filatov and I. v. Dement'yev. *Vop Virusol* 15(6):729-730, 1970.

Three strains of a human leukocytic leukemia virus (HLV) were isolated from leukocyte suspensions obtained from 5 leukemic patients. Inoculation of human leukocyte cultures with these HLV strains of the 5th passage increased the mitotic rates to 26, 20 and 16 per 1000, while the mitotic rates of a control culture or of a cell culture treated with a comparable fraction obtained from a healthy donor and passaged 4 times were 10 and 6 per 1000. The HLV strains exhibited poor stability; they were destroyed by ether and thermally inactivated at 60°C within 30 min. These strains were not pathogenic to laboratory animals such as rabbits, mice, rats, hamsters or guinea pigs. Differential centrifugation of HLV-infected cell culture homogenates in a CsCl gradient revealed that HLV had a buoyant density of 1.184 g/cm³ which corresponded to that of the avian or murine leukemia virus. Electron microscopy of these strains after gradient centrifugation revealed the presence of typical leukemia virus particles with a characteristic morphology. Viral particles were also noticed in the ultrathin slices of HLV-infected leukocytic cultures mainly in the cytoplasm. The structure and the parameters of these HLV strains were similar to those of the animal leukemia virus. The absence of β-globulins and a considerable increase in α₁-globulins were observed in the HLV-infected leukocytic cultures.

1419 SEARCH FOR A HUMAN BREAST CANCER VIRUS.

(E.) Moore, D. H. (Inst. Med. Res., Camden, N. J.), J. Charney, B. Kramarsky, E. Y. Lasfargues, N. H. Sarkar, M. J. Brennan, J. H. Bur S. M. Sirsat, J. C. Paymaster and A. B. Vaidya. *Nature* 229(5287):611-614, 1971.

Mammary milk from women from 3 distinct populations examined in order to locate viral particles similar to those found in the milk of mice with mammary tumors (B-type particles). The 3 populations were 156 women from the Philadelphia area with no family history of breast cancer, 10 women with histories of breast cancer in their families, and 46 women from the inbred Parsi community in Bombay, which has a high incidence of mammary cancer. Particles with the same morphological characteristics as those which are thought to cause breast cancer in mice were found in the milk of women in all 3 populations. B-type particles were found in 5% of milk samples from women with no familial history of breast cancer, in 60% of women with such a history and in 39% of Parsi women. Similarities between human and murine breast cancer, including the viral factor, the presence of family groups, appear to suggest that murine breast cancer is a valuable experimental model for human breast cancer.

1420 INFECTIVITY OF CELL CULTURES BY A VIRUS ISOLATED FROM A MAMMARY CARCINOMA OF A

RHESUS MONKEY. (E.) Chopra, H. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), I. Zell E. M. Jensen, M. M. Mason and N. J. Woodside. *J Cancer Inst* 46(1):127-137, 1971.

Propagation of a virus isolated from monkey mammary carcinoma was effected by cocultivation of the monkey embryo cells and tumor tissue. Virus particles

in the form of intracytoplasmic A-type particles and extracellular enveloped particles similar in appearance to those observed in the original tumor were isolated. Infected embryo cells revealed the presence of the intracytoplasmic particles one wk after virus inoculation with extracellular forms appearing at 10 days. Infected cells of monkey lung contained polyribosomes and rough endoplasmic reticulum. Chimpanzee lung cells which were infected were characterized by a well-developed endoplasmic reticulum and large numbers of mitochondria; intracytoplasmic A-type particles were seen in a few cells post-inoculation. Infected cultures of normal human leukocytes (NC37) showed typical blast cells, scanty endoplasmic reticulum, abundant free ribosomes, and a few mitochondria, whereas in human embryonic cell cultures the developmental pattern was identical to that seen in other cultures. In the absence of any apparent cytopathic changes, the visualization of intracytoplasmic A-type particles and their subsequent budding from the cell surface were the only criteria used to determine infectivity.

- 1421 OBSERVATIONS OF VIRUS IN VIRUS-INDUCED TUMORS IN HAMSTERS. (Fr.) Cesarini, J. P. (Reg. Anti-Cancer Ctr., Marseilles, France). *C R Acad Sci* 272(6):901-904, 1971.

The BHK 21/C 13 cells in culture as well as the clones obtained after transformation of these cells by oncogenic DNA and RNA virus contain a virus of a characteristic structure and development in their cytoplasm. This virus was not found in the *in vivo* virus-induced tumors in animals reared under the conditions described in this study. Systematic examination by means of electron microscopy was conducted in over 5000 healthy animals and in those with tumors induced by polyoma virus or by the injection of transformed cells. Subcultures of BHK 21/13, during its maintenance in culture, revealed the presence of a virus (H) with a central nucleoid and a clear center. The virus had a distinct topography and was present in the cell cytoplasm and in cisterns and dilated vacuoles. The H virus was found at times in association with C particles in inter- or intra-mitochondrial (RB 12) sites or with mycoplasma (CL 2 TSV 5). It was found in all strains of cultures whose origin was the BHK 21/13, and also in the tumors produced by injection of such strains, but was not found in the tumors which were originally induced by the polyoma virus (CT 54, CT 55). A similar viral structure has been described in cultures of calf kidneys.

- 1422 DISTRIBUTION OF INTRACISTERNAL A-PARTICLES IN A VARIETY OF NORMAL AND NEOPLASTIC MOUSE TISSUES. (E.) Wivel, N. A. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and G. H. Smith. *Int J Cancer* 7(1):167-175, 1971.

Neoplastic and non-neoplastic mouse tissues were examined by electron microscopy for the presence of intracisternal A particles. Non-neoplastic tissues harboring A-particles included the ectoderm of mammary glands and the mesoderm of seminal vesicles, ovaries and spleen. Malignant tissues containing

A-particles included the ectoderm of mammary adenocarcinomas, the mesoderm of plasmacytomas and Leydig cell tumors, and the endoderm of pulmonary adenomas, hemangioendotheliomas and hepatomas. A-particles usually measured 75-85 m μ in diameter, although some of the tumor cell particles were larger. The presence of particles in gonadal tissue of both sexes appeared to suggest that the particles may be transmitted vertically. It was noted that A-particles were found in most of the tissues known to support the replication of mouse leukemia and mammary tumor viruses. A-particles were seen to co-exist with viral C-type particles and with intracytoplasmic A-particles. Intracisternal A-particles may represent a marker for incomplete viral replication, representing the partial gene expression of an oncogenic RNA virus.

- 1423 AN UNUSUAL VIRUS IN CULTURES FROM A HUMAN NASOPHARYNGEAL CARCINOMA. (E.) Achong, B. G. (U. Bristol Med. Sch., England), P. W. A. Mansell, M. A. Epstein and P. Clifford. *J Nat Cancer Inst* 46(2):299-307, 1971.

Virus particles were found in cultured lymphoblastoid cells derived from a nasopharyngeal carcinoma from a Kenyan African. The tumor cell monolayer culture released the virus-bearing lymphoblastoid cells after 105 days in culture; 10% of the intact cells contained particles. Virus particles appeared in immature and mature forms. The immature form of particle was spherical, about 45 m μ in diameter, and had an electron-opaque outer zone and an electron-lucent center. These particles were present only in cytoplasm and passed through cell membranes by budding. The mature virus consisted of the immature spherical center surrounded by evenly spaced spines radiating from its surface. The overall diameter of the particle from spine tips was 110 m μ . Where cells were juxtaposed, the virus produced a thickening of the cell plasmalemma and a development of spines at the sites of viral budding. Although these virus particles could not be classified decisively, they were similar to feline fibrosarcoma virus and bovine lymphosarcoma virus, and had some of the features of the mouse mammary tumor agent.

- 1424 *IN VITRO* STUDIES OF RAT VIRUSES: II. EFFECTS OF HEAT, X-IRRADIATION AND CARCINOGENIC DRUGS. (E.) Lum, G. S. (VA Hosp., Cincinnati, Ohio). *Oncology* 24(6):416-430, 1970.

Incubation of rat viruses (strains L-S and RV) in rat embryo cell cultures at 42° produced lower virus titers than incubation at 37° by 0.75-1.0 logs; the depression of virus titer with high temperature was general; however, at day 6 of incubation L-S strain virus-infected cells were 0.5 log titers higher in cultures incubated at 42° than in cultures incubated at 37°. Incubation of cells at 42° produced virus 1 day later than incubation at 37°. Treatment of cultures with D₂O enhanced virus titers in cells incubated at 42°, producing a 3 log increase on day 3 of incubation. Exposure of virus-infected cells to 480 rads of X-irradiation delayed the cytopathic effect, but did not reduce virus titers; a decrease in virus

titers of 1.5 logs resulted from exposure to 800 rads. Virus-infected cells treated with 3-methylcholanthrene produced virus 135 days after treatment, while untreated cells infected with virus did not produce virus; treatment with 2-aminobiphenyl did not result in the emission of virus by infected cells. Increasing doses of benzo(a)pyrene caused cells to emit virus after decreasing period. Twelve and 8 μ g caused the virus-production cycle to begin after 7 and 8 days, resp.; 4 μ g caused the cycle to begin at 14 days. Urethan, methylbenzo(a)pyrene, cadmium sulfide and cadmium oxide also increased the amount of virus produced by infected cells. Mustargen did not affect the cycle of virus production, and thioTEPA decreased the amount of virus produced.

- 1425 HISTOLOGIC AND ELECTRON MICROSCOPIC OBSERVATIONS ON A TUMOR-BEARING VIPER: ESTABLISHMENT OF A "C"-TYPE VIRUS-PRODUCING CELL LINE. (E.) Zeigel, R. F. (Roswell Park Mem. Inst., Buffalo, N. Y.) and H. F. Clark. *J Nat Cancer Inst* 46(2): 309-321, 1971.

An edematous myxofibroma weighing 117.5 g was found in the precardial area of an adult female Russell's viper (*Vipera russelli*). Although no virus particles could be found in suspensions of tumor tissue, the morphology of the tumor cells was similar to those of a cell line (VSW) derived from the spleen of this tumor-bearing Russell's viper; this cell line has yielded viral C-type particles. The tumor was composed of sheets and cords of intensely-staining cells similar both to fibroblasts and to epithelial cells. Metastatic intravascular cells were found in spleen, kidney, liver and pancreas. Both primary and metastatic cells had desmosomes, tonofibrils, and large nuclei. Clusters of strongly basophilic cells in the venous lumina were also seen. The VSW cell line appears to have originated from tumor metastasis to the spleen.

- 1426 NEW CALIBRATION CORRELATIONS FOR MOLECULAR WEIGHTS OF CIRCULAR DNA: THE MOLECULAR WEIGHT OF THE DNA OF AN ONCOGENIC PAPOVA VIRUS OF THE SYRIAN HAMSTER. (E.) Bottger, M. (German Acad. Sci., Berlin, Germany), D. Bierwolf, V. Wunderlich and A. Graffi. *Biochim Biophys Acta* 232(1):21-31, 1971.

Interdependence between the sedimentation coefficient and molecular wt was studied through sedimentation analysis of the DNA of a Syrian hamster papova virus. Derivation of two equations for the closed ring form and for the open relaxed ring component II, $s_{11}^0 - 5.16 = 0.00439 M^{0.553}$ and $s_{11}^0 - 2.50 = 0.219 M^{.435}$, gave determinations of molecular wt which were 10-15% lower than values calculated according to other equations in use, showing an average of $3.1 \cdot 10^6$ which coincides closely with the molecular wt of $3.3 \cdot 10^6$ determined by electron microscopy. Two homogeneous DNA components were observed in addition to heterogeneously sedimenting material with sedimentation coefficients < 12 S; relative proportions showed the predominant heterogeneous component to be Component II, the open-relaxed ring component. The relation

of the expansion parameters in linear and circular DNA $e_{11}^0 = e_C^0$ is justified on the basis of present findings.

- 1427 HUMAN SARCOMAS IN CULTURE: FOCI OF ALTERED CELLS AND A COMMON ANTIGEN; INDUCTION OF FOCI AND ANTIGEN IN HUMAN FIBROBLAST CULTURES BY FILTRATES. (E) Giraldo, G. (Sloan Kettering Inst. Cancer Res., New York, N.Y.), E. Beth, Y. Hirshaut, T. Aoki, L. J. Old, E. A. Boyse and H. C. Chopra. *J Exp Med* 133(3):454-478, 1971.

Primary cultures of human osteosarcomas, leiomyosarcomas and fibrosarcomas were composed primarily of fibroblasts; these became more predominant in successive passages. Human sarcoma cultures usually started to proliferate after 4-6 wk in culture. Three of 7 cultured sarcomas developed into colonies of altered cells after 4-5 months in culture, and consisted of foci of randomly oriented crisscrossing cells. In some sarcoma lines, foci disappeared for periods of time and then reappeared; the appearance of foci at a particular time in a particular sarcoma culture was found to be characteristic of that sarcoma. In 12 of 23 attempts, foci were produced in human fibroblast cultures by filtered medium of sarcoma cultures within 1-2 wk from the time of introduction of the filtrate; no foci appeared in fibroblasts not exposed to filtrates. Induced foci were morphologically and ultrastructurally similar to spontaneous foci arising in sarcoma cultures. Electron microscopy failed to reveal evidence of viruses present in sarcoma cultures or in foci. When sera from patients with osteosarcoma were tested by indirect immunofluorescence for reaction with 7 sarcoma lines, positive reactions were elicited with 6 of these lines. Immunofluorescence also revealed a surface antigen in the cytoplasm of 12 of 15 sarcoma cultures; primary culture of sarcoma cells did not demonstrate surface antigen. No relationship was found between focus formation and antigenicity in sarcomas, or between the ability of sarcoma filtrates to induce foci in fibroblasts and antigenicity. Filtrates from 3-day-old sarcoma cultures induced the appearance of antigen in 0.01-1% of human fibroblasts.

- 1428 C-TYPE VIRUS PARTICLES IN PIG KIDNEY CELL LINES. (E.) Armstrong, J. A. (Natl. Inst. Med. Res., London, England), J. S. Porterfield and A. T. De Madrid. *J Gen Virol* 10(2):195-198, 1971.

A non-cytopathic virus morphologically similar to the oncogenic C-type virus particles was examined in pig kidney cells by electron microscopy. Extracellular rounded virus particles were found in the vicinity of 25% of cells; the particles measured 95-115 nm in diameter. The C-type particles were more common in the PS, PK15 and IB-RS-2 cultures of pig kidney cells than in SK6 cells. The particles consisted of an envelope separated by a zone of low density from a core of high density; the core was irregular in outline and often showed a fibrillar substructure. The core measured 60-85 nm in diameter. Particles budding off

ward from the cell surfaces were frequent. The significance of the observation of C-type virus particles in pig kidney cells, and the mode of their introduction into these cells, is obscure.

1429 PURIFICATION OF THYMIDINE KINASE ACTIVITY FROM YABA VIRUS INDUCED TUMORS. (E.)

Gordon, H. L. (Roswell Park Mem. Inst., Buffalo, N. Y.). *J Med* 1(2):110-116, 1970.

Cell-free extracts of monkey tumors induced by Yaba pox virus were subjected to acetic acid and ammonium sulfate precipitation in order to isolate the thymidine kinase of the tumors in a pure form. The precipitated enzyme was subsequently purified by DEAE-cellulose column chromatography. A 1.4-fold increase in activity was found in the acetic acid-precipitated fraction; precipitation of this fraction with 30% (NH₄)₂SO₄ resulted in a 2.5-fold increase in activity. Three protein fractions were separated on column chromatography, which showed thymidine kinase activity 102-fold, 100-fold and 45-fold greater than the activity-levels of the original reaction mixture.

1430 BIOPHYSICAL CHARACTERIZATION OF THE YABA TUMOR POX VIRUS. (E.) Fiel, R. J. (Roswell Park Mem. Inst., Buffalo, N. Y.), H. L. Gordon and R. F. Zeigel. *J Med Exp Clin* 1(3):142-155, 1970.

Yaba tumors were induced on the backs of stump-tailed Macaque and rhesus monkeys by s.c. inoculation of tumor homogenates; tumors were excised after 4 wk of growth, and the Yaba pox virus was isolated, purified and characterized by rate and isopycnic zone centrifugation, electron microscopy and small- and wide-angle light scattering methods. A single rate zonal centrifugation treatment eliminated 85-90% of total tumor protein without loss of virus. Isopycnic banding of the rate zonal fractions allowed isolation of 4 virus particles, designated L, M, N, and X. The banding density of particle L was 1.11, while that of M and N was 1.26; no banding density for X was recorded. Light scattering experiments indicated that particles L, M, and X all measured about 400 nm in diameter, while particle N measured about 500 nm. L particles were thought to be immature virions, while M particles were considered to be mature. N particles appeared to consist of aggregates of M particles. The nature and composition of the X particles remained unclear.

1431 RNA DEPENDENT DNA SYNTHESIS IN CELL FREE PREPARATIONS OF HUMAN LEUKEMIA CELLS. (E.)

Ackermann, W. W. (Dept. Epidem., U. Michigan, Ann Arbor), W. H. Murphy, B. A. Miller, H. Kurtz and S. T. Barker. *Biochem Biophys Res Commun* 42(4):723-729, 1970.

To test the possibility that human leukemia has a viral etiology, a continuous line of cells established from a case of human leukemia was selected and examined for RNA primed DNA polymerase activity. Incorporation of H³-thymidine phosphate into acid-insoluble material could be shown to be approximately

a linear function of the concentration of the enzyme with dilutions greater than 30% and was absolutely dependent upon the presence of MgCl₂, all 4 deoxy-ribonucleotide triphosphates and enzyme. Incorporation was reduced 78-83% by RNase treatment but was not markedly affected by a nonionic detergent or lysozyme; however, it was almost completely inactivated by trypsin. The acid-insoluble product into which ³H-thymidine phosphate was incorporated had the properties of DNA. The enzyme activity obtained from these cells is not distinctly different from that reported in tumorigenic virions, but there is no evidence that the active particle is a virion.

1432 INCIDENCE OF EB VIRUS-CONTAINING CELLS IN PRIMARY AND SECONDARY CLONES OF SEVERAL BURKITT LYMPHOMA CELL LINES. (E.) Maurer, B. A.

(Roswell Park Mem. Inst., Buffalo, N. Y.), T. Imamura and S. M. Wilbert. *Cancer Res* 30(12):2870-2875, 1970.

Burkitt lymphoma cell lines cloned by agar droplet and single-cell isolation procedures were examined for the presence of Epstein-Barr virus-containing cells by an indirect immunofluorescent antibody test. Of 10 parental cell lines tested using the agar droplet method, 6 were placed in a high-virus-incidence group and 4 in a low-virus-incidence group, separation being based upon whether the cell line had greater than or less than 1 fluorescent cell per thousand counted. Of 12 groups of clones produced from the high-incidence group, 8 were 100% positive. The range of Epstein-Barr virus positiveness for each group of clones was usually broader and lower than that of the parental culture with incorporation of 7S globulin showing no effect on incidence or range of positiveness. In the low-incidence group, when clones were established, all cultures produced at least 1 positive clone, with proportion of positive cells being equal to or greater than the parental culture; incorporation of 7S globulin had no effect on the incidence or range of positiveness. In clones derived from single Burkitt lymphoma cells, 6 cell lines were selected; 3 had an incidence of positive cells of greater than 1 cell per thousand and 3 showed negativity by indirect immunofluorescent testing. All single cell clones in the high-incidence group were virus positive and the range of positivity of derived clones was broader and lower than the range of parental cultures. The incidence of virus-positive clones derived from the low-incidence parental group of cultures by single-cell isolation was 8.5% and by the agar droplet method, 7.1%. Cloning efficiency for the single-cell isolation procedure ranged from 2 to 22% and no correlation between cloning efficiency and incidence of Epstein-Barr virus-containing cells was noted. A genetic potential for virus synthesis which is vertically transmitted from parent to daughter cell in the Burkitt cell lines studied is indicated from these studies.

1433 SOME BIOPHYSICAL ASPECTS OF E-B VIRUS ADSORPTION TO THE SURFACES OF THREE TYPES OF MAMMALIAN CELLS. (E.) Weiss, L. (Roswell Park Mem. Inst., Buffalo, N. Y.) and S. J. Horoszewicz. *Int J Cancer* 7(1):149-159, 1971.

Virus adsorption in human peripheral normal, leukemic and myelomatous blood cells with respect to electrokinetic properties of the cell surfaces was studied by immuno-fluorescent and electron microscopic techniques. Both RNase and neuraminidase produced significant reductions in cell surface net negativity, and the combination of the enzymes resulted in greater reductions than either one when used singly; a sharp diminution in the mean mobility of one type of virus-adsorbing cells was seen as calcium concentrations were altered. In non-adsorbing cells, the mean rate of decrease in surface negativity was highest as the concentration of environmental calcium increased, and in the virus-adsorbing cells, the mean rate of decrease was less marked. Treatment of the cells and virus suspensions with enzymes and varying calcium ion concentrations did not demonstrably change the pattern of cell-virus interaction compared to untreated controls. Electron microscopic examination revealed virus particles attached to 2 cell lines previously recognized to adsorb viruses in contrast to the absence of particles in the non-absorbing cell line used here, which was taken from a patient with multiple myeloma.

- 1434 ELEVATED ANTIBODY TITERS TO EPSTEIN-BARR VIRUS IN HODGKIN'S DISEASE. (E.) Levine, P. H. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), D. V. Ablashi, C. W. Berard, P. P. Carbone, D. E. Waggoner and L. Malan. *Cancer* 27(2): 416-421, 1971.

Indirect immunofluorescence tests were performed on sera from patients with Hodgkin's disease, normal controls, patients with non-malignant disease, and patients with lymphomas other than Hodgkin's disease, and the Epstein-Barr virus (EBV) antibody titers recorded from these groups were compared. Thirty-four percent of Hodgkin's disease patients had EBV antibody titers in excess of 1:640, while 11.9% of "other lymphoma" patients, 3.5% of non-malignant condition patients, and 4.7% of normal subjects had titers at this level. Geometric mean titers of EBV antibody for these 4 groups were 1:367 (Hodgkin's disease), 1:132 (other lymphoma), 1:162 (non-malignant pathology), and 1:91 (normal subjects). Patients with the mixed cellularity form of Hodgkin's disease had the highest geometric mean titers of antibody (1:736), and those with the nodular sclerosis type of Hodgkin's disease had the lowest geometric mean titers (1:177). Patients with high titers of EBV antibody generally had had symptoms of Hodgkin's disease for longer periods, were in more advanced stages of the disease, survived for shorter periods, and showed more lymphocyte depletion, than patients with low titers. Treated patients had higher titers than untreated patients. No differences were found between Hodgkin's disease patients and normal subjects in the titers of antibody to herpes simplex viruses types I and II, cytomegalovirus, or varicella. The findings did not indicate whether EBV has an etiological role in Hodgkin's disease as opposed to the role of a passenger virus ancillary to the genesis of the condition.

- 1435 FURTHER CHARACTERIZATION OF THE WI-L1 AND WI-L2 LYMPHOBLASTOID LINES. (E.) Levy, J. A. (San Francisco Med. Ctr., Calif.), D. N. Buell, C. Creech, Y. Hirshaut and H. Silverberg. *J Nat Cancer Inst* 46(3):647-654, 1971.

Attempts to isolate virus by inoculating cell free extracts of cells from 2 human lymphoblastoid cell lines onto monolayer cultures proved fruitless. The lymphoblastoid cell lines, designated WI-L1 and WI-L2, were originally derived from 2 patients, 1 with mycosis fungoides and 1 with hereditary spherocytic anemia. Although fluorescence studies had indicated that Epstein-Barr virus was present in line WI-L1, the virus could no longer be demonstrated after the line had been in culture for 6 months. Antibodies to Epstein-Barr virus were demonstrated in both cell lines and in all the members of the family of the donor of cell line WI-L2. Both cell lines were found to synthesize IgG-type molecules, and both had similar rates of IgG synthesis; IgG counts rose steadily from zero to 8,000 over 60 min in culture with ³H-leucine. A subline of cells from WI-L1 with a unique #1 chromosome having a subterminal secondary constriction was established.

- 1436 TRANSFORMATION AND DIFFERENTIATION OF RENAL TISSUE INDUCED BY A RNA VIRUS. (Fr.) Lacour, F. (Inst. Gustave Roussy, Villejuif, France), O. Weiler, R. Gerard-Marchant and E. Delain. *Bull Cancer* 57(3):335-344, 1970.

An avian myeloblastoma line was established in Leghorn chicks in renal tissue (DNV). The chicks were inoculated with an acellular extract corresponding to 0.3 g of tumor tissue and 3 successive transmissions were possible by the same technique. Examination by electron microscopy showed the presence of viral particles comparable to the avian myeloblastosis virus (AMV) of the primary tumor. The intrarenal tumor proliferation shows a predominance of blastomas with complex differentiation, both epithelial and mesenchymal. The virus exhibited a particular tropism for renal tissue. Although inoculated into a highly sensitive strain at an age most sensitive to leukemogenic virus, the virus appeared in renal tumors in 94% of the cases, and no leukemia or other malignant neoplasm was observed. The virus induces a malignant transformation of nephrogenic cells which then undergo all the types of cell differentiation from nephron alone to various connective tissue, bone or hemopoietic tissue.

- 1437 HETEROGENEITY OF STRAIN R AVIAN (ERYTHROBLASTOSIS) VIRUS. (E.) Ishizaki, R. (Duke U. Med. Ctr., Durham, N. C.) and T. Shimizu. *Cancer Res* 30(12):2827-2831, 1970.

Avian erythroblastosis virus strain R (AEV-R), an agent which produces erythroblastic leukemia in chickens, had an LD₅₀ of 10^{-4.5} ml of a 10% liver homogenate from leukemic birds of the 4th passage. Inoculated chickens responded by antibody or viremia

production to dilutions higher than those causing frank leukemia. Tests were performed to investigate the interference resistance of AEV-R against Rous-associated virus in chick embryo cells; interference was produced by a 10^{-6} dilution of virus in liver homogenate. Chick embryo cells were transformed by AEV-R in dilutions of 10^{-4} ; AEV-R foci were noted following inoculation of the chick embryo cells with 10^{-1} dilutions of virus. While the infectious capacity for chickens of AEV-R as measured by viremia and antibody production was 1000-fold greater than the capacity for leukemogenic activity, the virus' ability to infect chick embryo cells measured by interference was 10-fold less than its ability to induce leukemia in chickens. Passage of AEV-R in tissue culture reduced leukemogenic activity. AEV-R was neutralized by anti-Rous associated virus antiserum, suggesting that AEV-R is a member of virus subgroup B of avian tumor viruses. A component of AEV-R derived directly from chickens was found to infect but not to transform chick embryo cells, suggesting that AEV-R is heterogeneous.

1438 COMMON SEQUENCES BETWEEN RNA FROM ONCOGENIC VIRUSES AND CELLULAR DNA. (Fr.)

Harel, J. (Inst. Gustave Roussy, Villejuif, France), L. Harel and G. Frezouls. *Bull Cancer* 57(3):283-300, 1970.

Competitive hybridization experiments showed that only one fraction of RNA 65 S of avian myeloblastosis virus (AMV) can be hybridized at a high concentration with cellular DNA, and that this fraction of the viral RNA must be identical or quasi-identical with certain sequences of RNA normally transcribed in the non-infected cells of the chick. These results obtained after partial recurrent hydrolysis of RNA 65 S of AMV demonstrated that only a small fraction of cellular RNA, probably bound to cytoplasmic membranes, contained sequences identical with the hybridizable viral RNA sequence. These sequences were present in similar quantities in the intact as well as the virus-infected cells transformed by AMV; the same doses of cellular RNA of normal liver or myeloblasts inhibit almost completely the hybridization of RNA 65 S with the DNA of cells producing the virus. It is possible to envision from the results that the common sequences between the viral RNA and cellular DNA represent sites of attachment for future integration of the viral genome in the cellular genome.

1439 AN AVIAN LEUKOSIS VIRUS RELATED TO RSV(O): PROPERTIES AND EVIDENCE FOR HELPER ACTIVITY. (E.) Vogt, P. K. (U. Washington Sch. Med., Seattle) and R. R. Friis. *Virology* 43(1):223-234, 1971.

Inoculation of type C/A chick fibroblasts and Japanese quail fibroblasts with Rous sarcoma virus type O [RSV(O)] produced infectious progeny virus in 1.35% of Japanese quail cells and in 78% of chicken cells. The efficiency of virus-production among RSV(O) colonies in quail cells increased with increasing multiplicity of infection; undiluted virus inocula produced RSV(O) in 73% of cases, while virus

dilutions of 1:50 produced virus in 8.5% of cases. Apparently, the virus-producing colonies in chicken cells contained a helper agent which facilitated the reproduction of RSV(O); this agent could be transferred to quail cells. Treatment of quail fibroblasts with sonically disrupted transformed chicken cells enabled quail cells to produce virus in 100% of the fowl. The transmissible agent discovered in chicken cells was found to have all the attributes of an avian RNA leukosis virus with envelope antigens identical to those of RSV(O). The agent was designated Rous-associated virus type O [RAV(O)]. Quail cells were found to lack the group-specific antigen of the avian leukosis virus, while all chicken cells did harbor this antigen. RAV(O) apparently plays an essential role in the replication of RSV(O) in group-specific antigen-negative cells such as Japanese quail fibroblasts. RAV(O) did not interfere significantly with the plating efficiency of RSV(O) when cultures were co-infected with the 2 viruses. RAV(O) did not infect quail cells when inoculated alone in the absence of RSV(O).

1440 ISOLATION OF THE NUCLEIC ACID OF FELINE LEUKEMIA VIRUS. (E.) Jarrett, O. (Dept.

Biochem., U. Glasgow, Scotland), J. D. Pitts, J. M. Whalley, A. E. Clason and J. Hay. *Virology* 43(1):317-320, 1971.

RNA isolated from cultures of feline leukemia virus (FeLV) was found to be similar to RNA of the avian and murine leukemia viruses. The FeLV used was isolated from a cat with spontaneous alimentary lymphosarcoma and was grown in feline embryonic cells. The viral RNA was extracted by the SDS-phenol method and by the SDS-pronase method. The viral RNA separated on Sephadex G-100 columns into 2 components, 1 of which was excluded from the gel and appeared in the void volume and 1 of which eluted with the 4S marker cellular RNA. The former RNA showed a major 75S peak on sucrose gradient centrifugation. These 2 major components of the FeLV virus RNA are similar to those from other RNA tumor viruses.

1441 CURRENT INFORMATION ON FELINE AND CANINE CANCERS AND RELATIONSHIP OR LACK OF RELATIONSHIP TO HUMAN CANCER. (E.) Gardner, M. B. (U. Southern Cal. Sch. Med., Los Angeles). *J Nat Cancer Inst* 46(2):281-290, 1971.

In a study of 103 domestic cats, C-type feline tumor virus was found in 70% of cats with lymphoma, 20% of cats with sarcoma, and in 20% of cats with carcinoma. Virus has also been found in livers of fetal cats at 3-7 wk gestation. The feline virus has been isolated from a spontaneous feline fibrosarcoma and its inoculation has produced sarcomas in monkeys, kittens, puppies and rabbits. In tissue culture studies, feline, canine and human embryo cells were found to be susceptible to transformation by feline virus; viral particles were released from transformed cultures. Human tumors were transmissible to fetal cats using cloned human sarcoma cells which were either infected or uninfected with feline virus. No causal relationship has been found between virus-

associated cancers of cats and human or canine cancers; cats apparently do not spread feline virus to dogs or to men. The virus is probably inherited among cats but it may be transmitted in bites or scratches.

- 1442 INTRACISTERNAL VIRAL PARTICLES IN MURINE LEUKEMIAS. (E.) Braylan, R. C. (Nat'l. Acad. Med., Buenos Aires, Argentina), L. Z. De Tkaczewski, M. E. M. Colmerauer and C. Dosne Pasqualini. *Medicine* 30(5):459-464, 1970.

Leukemia was induced in inbred mice by intrasplenic injections of allogenic leukemia cells, by syngeneic leukemia cells administered in subthreshold s.c. doses, or by i.p. injections of acellular supernatants of homogenized leukemic tissues. These leukemias killed host mice by 70 days postinoculation and were diagnosed as lymphoblastic leukemias characterized by massive infiltration of poorly differentiated lymphoblasts. Under the electron microscope, leukemia cells from mesenteric lymph nodes and s.c. leukemic infiltrations showed intracisternal A type virus particles and, rarely, A particles were seen budding from cellular membranes. Particles seen in the cisternae measured about 70 nm in diameter, were spherical, and showed varying electron density. The particles apparently emerged from thickenings of the rough endoplasmic reticulum. The association of intracisternal A particles with A and C particles in and around the same cell was striking. Intracisternal A particles may be as important in the mechanism of leukemogenesis as the classic A and C particles.

- 1443 EARLY MORPHOLOGICAL CHANGES ASSOCIATED WITH INFECTION BY A MURINE NONTHYMIC LYMPHATIC TUMOR VIRUS. (E.) Rabstein, L. S. (Microbiol. Ass., Walkersville, Md.), A. F. Gazdar, H. C. Chopra and H. T. Abelson. *J Nat Cancer Inst* 46(3):481-491, 1971.

One-day-old mice given i.p. inoculations with 1.5 infectious U of a strain of Moloney leukemia virus (MLV-A) developed solid lymphatic tumors which became noticeable by 12 days after inoculation of virus, and which left only 2 of 90 mice alive at 26 days post-inoculation. The spleen wt in the inoculated group increased significantly compared to that in uninoculated groups. Tumors began to appear on the meninges on day 14; the earliest evidence of tumor infiltration within the spinal cord coverings was seen microscopically on day 18. Visible and palpable nodes were first noted on day 18; they grew rapidly thereafter, with tumors appearing first in the cortical area. Preneoplastic changes in lymph node tissue included abundant polymorphonuclear leukocytes and pyknotic lymphocytic nuclei. Grossly enlarged spleens were evident on day 14, and myelotic cell precursors began to increase in bone marrow on day 12. Tumors consisted chiefly of lymphoblasts which grew rapidly in all cases and were markedly invasive. There were no signs of leukemic development in the blood of infected animals, and neither kidney, liver, nor adrenal glands were involved. Budding type-C virus par-

ticles were seen in tumor tissue and in nontumorous tissue in the spleen, marrow, thymus and dura.

- 1444 STREPTOVARICINS INHIBIT RNA DEPENDENT DNA POLYMERASE PRESENT IN AN ONCOGENIC RNA VIRUS. (E.) Brockman, W. W. (Johns Hopkins U. Sch. Med., Baltimore, Md.), W. A. Carter, L. H. Li, F. Reusser and F. R. Nichol. *Nature* 230(5291):249-250, 1971.

Reaction mixtures containing Moloney strain murine leukemia virus and streptovaricins in amounts ranging from 20-400 µg/ml significantly inhibited the RNA dependent DNA polymerase activity in the virus. A streptovaricin complex containing 7 macrolides as well as undetermined components produced 77% inhibition at 40 µg/ml doses; increase of the streptovaricin dose to 100 and 400 µg/ml gave inhibitions of 77% and 68%, resp. Streptovaricin C resulted in a 73% inhibition of RNA dependent DNA polymerase at 400 µg/ml, and streptovaricin A produced 33% inhibition at the same dose. Streptolydigin and rifampicin caused 3 and 13% inhibition, resp., while rifamycin SV inhibited polymerase activity 77% at 400 µg/ml.

- 1445 SENSITIVITY OF JLSV-9 CELLS TO MOLONEY LEUKEMIA VIRUS IN RELATION TO CELL CYCLE. (E.) Gergely, L. (Karolinska Inst., Stockholm, Sweden), M. Cikes, E. Klein, E. M. Fenyö and S. Friberg. *Exp Cell Res* 64(1):230-232, 1971.

Infection parameters, including mitotic index, modal cell volume, ³H-thymidine incorporation, and membran antigen appearance were investigated in synchronized cell cultures of JLSV-9 cells inoculated with Moloney leukemia virus (obtained from a YAC ascites lymphoma). Cell cultures were inoculated with 1 ml of a 1:100 dilution of the virus. The mitotic index of the infected cells dropped sharply from 0.95 to 0.10 by 1 hr after colcemid release of the synchronized cell, and thereafter remained at or near the lower level. Modal cell volume also dropped abruptly between 0-5 hr after colcemid release, decreasing by a factor of 2, and recovered by 13 hr after colcemid release, returning to near initial values. Tritiated thymidine increased precipitately following colcemid release, values rising from 2.0 cpm x 10³ at 0 hr to 20 cpm at 6 hr; thereafter, ³H-thymidine incorporation declined to 3.0 cpm at 15 hr after colcemid release. Antigen positive cells began to appear in cultures at day 18 after the initiation of cultures. Culture infected with virus 2-5 hr after metaphase arrest had higher antigenicity than other cultures. By day 35 the different cell cultures had similar proportions of membrane antigens.

- 1446 FORMS OF DEOXYRIBONUCLEIC ACID PRODUCED BY VIRIONS OF THE RIBONUCLEIC ACID TUMOR VIRUSES. (E.) Manly, K. F. (Massachusetts Inst. Technol., Cambridge), D. F. Smoler, E. Bromfeld and D. Baltimore. *J Virol* 7(1):106-111, 1971.

Sucrose gradient sedimentation of the DNA produced by DNA polymerase in murine leukemia viruses (Moloney

strain) showed that the DNA product consisted of 2 fractions: one fraction sedimented at the same rate as native viral RNA (60-70S) and was called the fast fraction; the other fraction sedimented at less than 15S (the slow fraction). The fast fraction contained most of the DNA product after 20 min of reaction; by 120 min of the reaction the slow fraction contained most of the DNA product. Enzyme analysis with enzymes of known specificity showed that the slow fraction from a 120 min reaction consisted of 50% single-stranded DNA and 40% double-stranded DNA, and of 10% hybrid DNA; after a 20 min reaction the slow fraction consisted of 70% single-stranded DNA, 15% hybrid DNA, and 15% double-stranded DNA. After a 120 min reaction the fast fraction consisted of 40% single-stranded DNA, 35% hybrid DNA, and 25% double-stranded DNA. After a 20 min reaction, the fast fraction consisted of 45% single-stranded DNA, 45% hybrid DNA, and 10% double-stranded DNA. Findings of the relative proportions of single-stranded, hybrid and double-stranded DNA were confirmed by analysis on CS_2SO_4 gradients. In the presence of actinomycin D, the predominant DNA product was single-stranded. The variation in type of DNA produced by the virions may be accounted for by a model involving the successive displacement of single-stranded DNA as it is produced by double-stranded DNA; this conversion of single- to double-stranded DNA, according to the model, is obstructed by actinomycin D.

1447 RELEASE OF C-TYPE PARTICLES FROM NORMAL RAT THYMUS CULTURES AND THOSE INFECTED WITH MOLONEY LEUKEMIA VIRUS. (E.) Teitz, Y. (Israel Inst. Biol. Res., Ness-Ziona), E. H. Lennette, L. S. Oshiro and N. E. Cremer. *J Nat Cancer Inst* 46(1):11-23, 1971.

The amount of Moloney leukemia virus particles released into the media of rat thymus cell cultures was studied through determination of uridine- 3H incorporation into virus particles purified from the culture medium. Differences in radioactivity as high as 20-fold were seen in sucrose gradient fractions (density 1.16-1.18 g/ml) obtained from 100 ml of culture fluids, and no great differences in the rate of incorporation of uridine- 3H and thymidine- 3H into the RNA and DNA of the cells were noted. Cultures chronically infected with the leukemia virus incorporated uridine- 3H into cellular RNA at a linear rate for 6-8 hr. A 6-hr exposure to 0.5 μg actinomycin D/ml resulted in 96% inhibition in uridine- 3H incorporation, 0.2 μg /ml in 90% inhibition and 0.1 μg /ml in 50% inhibition, while 0.05 μg /ml caused no inhibition; cytosine arabinoside (10 μg /ml) or 5-fluorodeoxyuridine (100 μg /ml) produced no inhibition. Noninfectious C-type particles were isolated from control cultures which were not specifically precipitated with anti-Moloney leukemic virus serum. Sensitivity to actinomycin D action seems to characterize all members of the avian and murine leukemia groups, possibly indicating the requirement for cell-specific RNA synthesis at some stage of viral maturation.

1448 RAUSCHER VIRUS-INDUCED LEUKAEMIA IN MICE: THE ROLE OF 7 S AND 19 S ANTIBODIES IN THE STIMULATION OR INHIBITION OF THE LEUKAEMOGENIC

PROCESS. (Rus.) Ter-Grigorov, V. S. (P. A. Herzen Res. Inst. Oncol., Moscow, U.S.S.R.), B. I. Shevelev, O. Ya. Moskovkina and V. M. Bergolz. *Biull Eksp Biol Med* 71(1):61-64, 1971.

Immunological features of the 7 S and 19 S fractions of Rauscher virus (RV)-infected mouse serum were investigated. Two groups of C57BL/6 mice 1-1½-month-old were used: I) 50 mice were given i.v. 0.4 ml of plasma from leukemic BALB/c mice; II) 50 mice were given i.v. 0.2 ml of the same plasma at a 1:24 dilution (low dose). Twenty-five mice of each group were given complete Freund's adjuvant (FA) at this time. A third group (III) of BALB/c mice was given i.v. 0.3 ml of the RV-infected C57BL/6 mouse serum fractions (24 hr after infection) in order to determine its effects upon leukemogenesis. The 19 S antibodies comprised the first peak of immune response against the group specific antigen (GSA) in the low dose RV-treated mice 8 days after administration. Both the 19 S and 7 S fractions were found to be cytotoxic at the beginning stage of the next peak of immune activity against the type specific antigen (TSA) 26 days after the beginning of the experiment while later (40 days after viral infection) cytotoxicity was found to be determined by 7 S antibodies only. The low titer RV-infected mice exhibited an involutive pattern of leukemia. A minor early peak of immune activity due to 19 S antibodies and no other cytotoxic effects were seen in the high dose RV-infected mice; the cytotoxic effects of antibodies from the 19 S fraction directed against the GSA were blocked by the continuous presence of antibodies from the 7 S fraction. Most of these mice died of leukemia at the end of the 3rd month. Leukemogenesis in BALB/c mice (group III) was found to be stimulated by the 7 S fraction from the high dose RV-infected and by the 7 S serum fraction of the anti-GSA (first peak) of the low dose RV-infected mice; the 7 S fractions with peak anti-TSA activities had an inhibitory effect on the development of leukemic colonies in the spleen of the BALB/c mice. The immunological mechanism of the irreversible suppression by FA of the resistance against RV in the C57BL/6 mice seemed to be related to the stimulation of 7 S antibody formation against the GSA; these antibodies had high leukemogenic stimulating effects *in vivo*, and were able to block the cytotoxic effects of the 19 S antibodies *in vitro*.

1449 PREVENTION OF GROSS VIRUS-INDUCED LEUKEMIA IN PROGENY OF IMMUNIZED FEMALE RATS. (E.) Ioachim, H. L. (Lenox Hill Hosp., New York, N.Y.). *Cancer Res* 30(11):2661-2664, 1970.

The prevention of leukemia in the offspring of female rats immunized with Gross leukemia virus (GV) was investigated. Female rats from 3 strains were given a single i.p. injection of 0.5 ml of GV stock undiluted within 1 month before the first 2 wk of pregnancy; the number and interval of the doses was varied in some rats. The offspring of these treated rats were injected i.p. with leukemia-inducing doses of GV (0.1 ml of a 1/10 dilution of GV). Leukemia was prevented in offspring by maternal injection of GV in 100% of cases, while all control rats born from the mothers not

given GV died with thymoma and lymphoid leukemia 62-90 days after injection with GV. Average latency for development of leukemia in nonimmunized rats was 71-75 days. Four of 5 sera from immunized mothers gave a 4+ type-specific reaction in complement fixation tests with the AKR virus antigen; sera from the 2 nonimmunized mothers were negative in this test.

- 1450 EFFECTS ON FRIEND DISEASE OF DOUBLE-STRANDED RNA OF FUNGAL ORIGIN. (E.) Pilch, D. J. F. (Beecham Res. Lab., Betchworth, Surrey, England) and D. N. Planterose. *J Gen Virol* 10(2):155-166, 1971.

The effects on splenomegaly associated with Friend virus-induced leukemia of treatment with a double-stranded RNA obtained from a penicillium culture were investigated in mice infected with Friend virus. Male mice were given a single i.p. injection of double-stranded RNA (100 µg/mouse) at various times. Enhancement of splenomegaly followed injection of the fungal RNA when the injection was given between 5 days before to 3 days after infection of mice with virus. The mechanism of enhancement of splenomegaly was probably related to the immunosuppressive activity of the fungal RNA. Inhibition of splenomegaly followed injection of RNA when the RNA was injected 7-11 days after virus infection. This regression of splenomegaly was rapid; in 1 experiment inhibition of splenomegaly was noticed on day 14, and the RNA had been injected the day before. Inhibition of splenomegaly may have been related to interferon induction by the fungal RNA, or to a more specific antiviral or anti-tumor effect. In 1 group of mice given RNA on the 10th day after virus infection, the mice remained free of splenomegaly symptoms for some time, but by the 10th wk after RNA injections, 70% showed splenomegaly. Multiple injections of 50 µg RNA produced effects on splenomegaly similar to the effects produced by a single 100 µg injection. The spleens of mice in which splenomegaly was reduced by RNA injection had a normal structure.

- 1451 EFFECT OF 7,12-DIMETHYLBENZ(a)ANTHRACENE ON PHAGOCYTOSIS AND ANTIBODY FORMATION IN FRIEND VIRUS LEUKEMIA. (E.) Elliott, S. C. (Dept. Microbiol., U. Arizona, Tucson) and G. T. Schloss. *Infect Immun* 3(2):217-220, 1971.

Experiments were carried out to study the effect of 7,12-dimethylbenz(a)anthracene (DMBA) on phagocytosis and antibody formation in the spleen and on phagocytosis in the liver of BALB/c mice with Friend virus leukemia, utilizing carbon clearance and microtiter techniques. The phagocytic index K (measuring the carbon clearance of the entire animal) at 5 and 15 min was elevated in Friend virus-infected mice throughout the experiment; DMBA showed no significant effect on the phagocytic index of normal controls or infected animals. At 5 and 15 min, a progressive decrease of index α (measuring phagocytic activity/wt liver and spleen) was noted in infected animals. A significantly higher α was seen

in infected animals with DMBA. No real difference in carbon content in either spleen or liver at 5 or 15 min after injection was noted in controls and infected animals. In the normal spleen, dense columns of carbon-laden phagocytes surrounding the lymphocytic nodules were seen; in the normal liver Kupffer cells were found to contain large amounts of carbon. In the infected animals, when splenic architecture was destroyed, the number of carbon-containing phagocytes was small and no carbon was present in neoplastic cells of either liver or spleen. Serum hemolysin titers in infected animals were higher at the end of week 1, remained in the same range through weeks 2, 3 and 4, and became lower during weeks 5 and 6 when compared to controls. Treatment of infected animals with DMBA produced higher hemolysin titers than controls at the end of weeks 1, 2, 5 and 6 and titers within the same range as controls during weeks 3 and 4. Correlation of decreased carbon uptake by the spleen and decreased production of serum hemolysin would be possible only if the phagocytes which take up carbon were the same cells involved in the immune stimulus.

- 1452 ULTRAVIOLET INACTIVATION OF MURINE LEUKEMIA AND SARCOMA VIRUSES. (E.) Yoshikawa, H. (Fac. Sci. Orsay, France). *Int J Cancer* 7(1):131-140, 1971.

Friend leukemia viruses and murine sarcoma viruses were exposed to UV in order to investigate the sensitivity of these viruses to inactivation by UV; inactivation was assayed *in vitro* by the interference of UV-irradiated virus with focus-formation by murine sarcoma virus. For both viruses, the UV inactivation dose was 2,000-3,000 ergs/mm². The relative number of murine sarcoma virus foci/culture plate increased with increasing dilution of the preparation of irradiated Friend virus. The fraction of Friend virus surviving UV irradiation enlarged as the dose of UV administered decreased; at UV doses of 6,000 ergs/mm², the survival fraction was less than .01, while at UV doses of 2,000 ergs/mm², the survival fraction was about .1. It was found that murine sarcoma virus produced by cells incubated with 5-fluorouracil was more sensitive to UV-inactivation than control virus which were not incubated with 5-fluorouracil, a finding which may suggest that the viral nucleic acid was sensitized by the base analogue. Murine sarcoma virus which survive UV irradiation showed a prolonged latent period, possibly due to the interference of inactivated virions with the growth of surviving virions. In general, murine sarcoma virus inactivated by UV in the presence of excess Friend virus showed survival rates which were related to UV dose and were similar to survival rates of murine sarcoma virus inactivated by UV in the absence of Friend virus. When UV-irradiated murine sarcoma virus was titrated on the cells previously irradiated with UV, the slope of the inactivation curve was steeper than when the virus was titrated on the normal cells, suggesting that the UV-damaged viral genome may have been complemented by the corresponding homologous host genome.

453 INDUCTION AND REGRESSION OF FRIEND LEUKEMIA IN VACCINATED MICE BY MEANS OF PARABIOSIS. (E.) Takizawa, K. (Inst. Med. Sci., U. Tokyo, Japan) and T. Yamamoto. *Gann* 61(6):605-606, 1970.

Induction and regression of Friend leukemia virus-induced splenomegaly in hyperimmune DDD mice was studied by means of parabiosis. When splenomegalic mice were parabiotically united for 10 days with other DDD mice which had been vaccinated weekly 10 to 15 times with formalin-inactivated Friend virus preparation, splenomegaly was induced in the vaccinated mice. The parabionts killed on the 10th day had spleens similar in wt to the vaccinated and non-vaccinated animals (ranging from 1.62 to 2.25 g). Parabionts observed 1 month after separation from the non-vaccinated partners had spleens which had decreased to approximately normal wt (ranging from 0.25 to 0.45 g) and infectious Friend virus was not detected; non-vaccinated partners died within 20 days after separation. After 3 months, no evidence of a splenomegalic recurrence was found in the vaccinated survivors. Parabionts kept in union died within 50 days after joining. Prolongation of the parabiotic union from 10 days to 20 days resulted in a failure of the spleen to return to normal size in some of the vaccinated animals after separation, and splenomegaly continued until death. This model seems to be a useful means for analyzing induction and regression of leukemia when the primary focus is surgically removed.

454 FLUCTUATING VIRUS AND ENZYME LEVELS IN PLASMA OF MICE INFECTED WITH THE FRIEND LEUKEMIA VIRUS. (E.) Buscher, T. J. (Dept. Microbiol. Guelph, Ontario, Canada), C. Frantsi and K. F. Gregory. *Canad J. Microbiol* 17(3):315-321, 1971.

The nature and cause of the plasma enzyme fluctuations in Friend leukemia virus (FLV)-infected mice was studied in 8-wk-old female Connaught strain mice by various assay techniques. A strain of FLV, which was confirmed to be free of lactate dehydrogenase elevating virus (LDV) by comparison of the effects of FLV on plasma lactate dehydrogenase (LDH) with those of purified LDV, was used in these experiments. Pronounced fluctuation in plasma LDH in mice infected with FLV was seen as 3 dose-dependent peaks which were 20-20 times above the normal levels. The magnitude of the peaks varied from 2.0 to 44 IU/ml with a mean of 9.4 U/ml compared to the normal mean of 0.35 U/ml. Simultaneous infection of 5 mice with Friend leukemia virus and the LDH elevating virus resulted in 4-9-fold elevations in plasma LDH within 2-3 days with secondary rises noted 5-8 days post-infection giving peak titers of 5-16 U/ml (14 to 46-fold increase). The same degree of elevation occurred in mice inoculated with LDH elevating virus. Plasma virus titers compared closely with plasma enzyme levels; mice were shown to produce interferon in response to infection with the LDH elevating virus of about 40 U/ml at 20 hr post-inoculation. The possibility that interferon at levels below the sensitivities of the assay systems could be has not been excluded. Isocitrate dehydrogenase, aldol-

ase and glutamic-oxalacetic transaminase showed similar fluctuations.

1455 EFFECT OF ADENOVIRUS TYPE 12 ON TUMOR INDUCTION BY SV40 AND PARA (DEFECTIVE SV40). (E.) Butel, J. S. (Baylor Coll. Med., Houston, Tex.), J. L. Melnick and S. S. Tevethia. *Int J Cancer* 7(1):112-118, 1971.

The tumorigenicity of combined defective SV40 (PARA) and adenovirus was investigated by injecting hamsters with PARA transcapsidated from adenovirus 7 to the Huie strain of adenovirus 12. The PARA-adenovirus 12 inoculum produced SV40-type tumors in 3 of 11 hamsters in approximately 5 wk postinoculation. Twenty wk postinoculation, no tumors had appeared in hamsters given SV40 alone; the latent period for tumors induced by Huie adenovirus 12 was 5 wk. The addition of SV40 to the Huie adenovirus 12 inoculum had little effect on tumorigenicity or latency. In hamsters given Huie adenovirus 12 alone, SV40 and adenovirus 12, or PARA-adenovirus 12, the percentage of animals developing tumors was approximately 50%. PARA-adenovirus 7 and adenovirus 12 produced tumors in 7 of 25 hamsters, beginning 5 wk postinoculation. Tumors induced by PARA-adenovirus 12 contained SV40 and adenovirus tumor antigens, while tumors induced by virus combinations lacking PARA lacked SV40 antigen. SV40 trans-plantation antigen was detected in tumors induced by PARA-adenovirus 12.

1456 ADENOVIRUS TYPE-12-INDUCED TUMOR IN MICE: CHARACTERIZATION OF A TUMOR CELL LINE. (It.) Pauluzzi, S. (Inst. Infect. Dis., U. Perugia, Italy), M. P. Zeppa and A. Piras. *Boll Ist Sieroter Milan* 49(5):448-460, 1970.

Adenovirus type 12 (8.5×10^5 PFU) inoculated into 13 newborn C3H/He inbred mice induced transplantable s.c. tumors in 3 mice after an average latency period of 173 days. Both *in vivo* and *in vitro* (mouse embryo cell cultures) virus-induced neoplastic structures appeared to be undifferentiated and consisted of clusters of small embryonal type cells specific to adenovirus type 12-induced tumors. The continuous cell line obtained from these tumors was transferred *in vitro* through 80 passages and appeared to have medium sized cells with a saturation density of 302,000 cells/cm². The oncogenicity of these cells appeared to be low when inoculated s.c. and much higher when inoculated intracerebrally. Specific tumor antigens were detected as fleck structures within their cytoplasm and as fine granules within the nucleus. Immunity to adenovirus type 12-transformed cells could not be induced.

1457 DEVELOPMENT OF NONONCOGENIC SA7-ADENOVIRUS 2 POPULATIONS THAT IMMUNIZE AGAINST SA7-TRANSFORMED CELLS. (E.) Kaplan, P. M. (Baylor Coll. Med., Houston, Tex.), J. L. Melnick and S. S. Tevethia. *J Nat Cancer Inst* 46(3):565-576, 1971.

Green monkey kidney cell cultures infected with simian adenovirus 7 (SA7) and human adenovirus 2 (Ad2)

yielded populations of SA7-Ad2 virus which, when treated with anti-SA7 or anti-Ad2 antiserum and inoculated into green monkey cell cultures, showed that the SA7-Ad2 virus had the antigenic properties of the Ad2 parent; anti-Ad2 antiserum completely inhibited plaque formation by the virus. All SA7-Ad2 populations induced synthesis of SA7 tumor antigen in simian cells; the SA7 tumor antigen was located in both nucleus and cytoplasm of infected cells. Ad2 antiserum, but not SA7 antiserum, inhibited the induction of synthesis of tumor antigen, suggesting that the genome which coded for SA7 tumor antigen existed within an Ad2 viral coat. Progeny virus from plaques induced in human embryo kidney cells by SA7-Ad2 virus grew in human embryo kidney cells but not in simian cells, while progeny from plaques produced in simian cells by SA7-Ad2 grew in human and simian cells. Plaque formation by SA7-Ad2 virus in simian cells was enhanced more than 10-fold by infection of cells with excess helper Ad2 virus. Plaque formation by SA7-Ad2 in simian cells showed 2-hit kinetics, suggesting that the virus particle which complemented plaque formation by Ad2 in the previous experiment is defective and cannot replicate independently of helper Ad2 virus. Although simian cells were abortively infected by Ad2, cells infected with both SA7 and Ad2 showed a 2,500-fold increase in virus production from 6-72 hr after virus infection. SA7-Ad2 virus containing the defective SA7 complementarity particle produced no tumors in hamsters, but SA7 alone induced tumors in 65% of inoculated hamsters; SA7-Ad2 virus did induce SA7 transplantation immunity in hamsters.

- 1458 A TEMPERATURE-SENSITIVE MUTANT OF ADENOVIRUS 31, DEFECTIVE IN VIRAL DEOXYRIBONUCLEIC ACID REPLICATION. (E.) Suzuki, E. (Nat'l. Inst. Hlth., Tokyo, Japan) and H. Shimojo. *Virology* 43(2):488-494, 1971.

The physiological activity of a temperature-sensitive mutant (ts 13) of adenovirus 31 was analyzed by means of DNA polymerase and thymidine kinase activity monitoring. The ts 13 mutant induced synthesis of T antigen, DNA polymerase and thymidine kinase but did not synthesize viral DNA and capsid protein at the nonpermissive temperature (39.5°C). The temperature shift-down test showed that the function of a gene ts 13 must be expressed for viral DNA replication during the period of 16-24 hr postinoculation, whereas the temperature shift-up test showed that protein synthesized at low temperatures was either rapidly exhausted or inactivated at high temperatures. Although tumors were produced in hamsters by ts 13 at 37.5°, it is not known whether transformation of cells occurs at nonpermissive temperatures.

- 1459 HAMSTER TUMORS INDUCED BY TYPE I AVIAN ADENOVIRUS (CELO): I. HISTOPATHOLOGY AND NEOANTIGEN OF VIRUS-INDUCED AND TRANSPLANTED TUMORS. (E.) Miller, L. T. (Dept. Anim. Path., U. Rhode Island, Kingston), V. Jasty, L. O. Mancini and V. J. Yates. *Arch Ges Virusforsch* 32(2-3):221-228, 1970.

Chicken-embryo-lethal-orphan avian adenovirus type I (CELO) were injected into hamsters in amounts of 0.1

ml of virus suspension; other hamsters were given transplants of CELO-induced fibrosarcomas or injections of tumor homogenates. Twenty-nine fibrosarcomas were induced by these procedures in the dorsolateral region or cheek pouches, and the tumors ranged in size from 7-90 mm in diameter. Tumors induced by viral inoculation and by transplant were similar histologically; all were fibrosarcomas with areas of increased vascularity, hemorrhage and necrosis. Variable amounts of intercellular collagen were found, depending on the extent of differentiation attained by the tumors. Virus-induced tumors showed cellular pleomorphism with prominent bizarre multinucleated giant cells; transplanted tumors showed fewer bizarre giant cells and increased mitotic activity. Results of immunofluorescence tests indicated a CELO-specific antigen in virus-induced and transplanted tumors; in all cases, fluorescence was restricted to the cytoplasm surrounding the nuclear envelope. Viral antigen was not detected.

- 1460 INFLUENCE OF HOST CELL ON BIOLOGIC MARKERS OF TYPES 1 AND 2 *HERPESVIRUS HOMINIS*. (E.) Stubbs, K. G. (Med. Ctr. U. Alabama, Birmingham), E. Snider and C. A. Alford, Jr. *J Infect Dis* 123(1):169-177, 1971.

The infectivity of wild *Herpesvirus hominis*, types I and II, was investigated in primary rabbit kidney cells, diploid human lung cells, primary human amnion cells, and African green monkey kidney (AGMK) cells. At 24 hr after infection of cultures with virus, *Herpesvirus hominis* type I produced amounts of infectious virus comparable to that produced by *Herpesvirus hominis* type II; however, virus titers produced by type I were somewhat higher than titers produced by type II, a difference especially notable in human diploid lung cells and primary human amnion cells. By 48 and 72 hr postinfection, extracellular infectivity of type I was consistently and markedly higher than that of type II in all cell systems except AGMK cells. In primary rabbit kidney cells, diploid human lung cells, and primary human amnion cells, type I extracellular infectivity was higher than that of type II by 6-20 fold at 24 hr, 8-800 fold at 48 hr and 25-600 fold at 72 hr. In AGMK cells, infectivity of type I and type II remained similar through 72 hr postinfection, with type II infectivity slightly higher than type I infectivity as a rule. Cell-associated infectivity of type I virus was also higher than that of type II virus in primary rabbit kidney cells; type II had higher levels of cell-associated infectivity than type I in AGMK cells. Infectivity of type I virus in AGMK was 50 times more sensitive to inhibition by 5-iodo-2-deoxyuridine than type II virus. Both differential infectivity characteristics and susceptibility to inhibition by 5-iodo-2-deoxyuridine were retained by the 2 types of virus through repeated cell passages, indicating that these 2 properties of the virus types may be useful markers for recognizing wild type *Herpesvirus hominis*.

- 1461 ISOLATION AND CHARACTERIZATION OF A HERPESVIRUS-LIKE (HSIUNG-KAPLOW) VIRUS FROM GUINEA PIGS. (E.) Bhatt, P. N. (Yale U. Sch. Med., New Haven,

onn.), D. H. Percy, J. L. Craft and A. M. Jonas.
Infect Dis 123(2):178-189, 1971.

herpeslike virus which demonstrated a spontaneous cytopathic effect (CPE) was recovered from guinea pig lung and kidney cell cultures and from trypsinized kidney cell cultures. The virus was isolated from 13 of 17 lung-explant cultures, from 2 of 12 kidney explant cultures, and from 10 of 15 trypsinized kidney cell cultures. No CPE was produced by inoculating guinea pig kidney cell cultures with supernatant from triturated virus-positive tissue cultures. Spontaneous CPE usually appeared within 1-2 wk in trypsinized kidney cultures, and in 2-3 wk in lung-explant cultures. Virus extracted from infected cultures inoculated into other guinea pig cell cultures resulted in the production of viruses by the inoculated cultures; kidney cell cultures showed the highest titers of virus ($6.7-7.0 \log_{10}/0.1 \text{ ml}$). The herpeslike virus was neutralized by rabbit antisera prepared against a previously isolated herpeslike virus and the latter virus was neutralized by antisera to the newly-isolated herpeslike virus. 5-Bromodeoxyuridine at concentrations of 10^{-5} M inhibited the multiplication of the virus in guinea pig kidney cell cultures. The virus produced no pathological effects in experimentally inoculated guinea pigs, mice, rhesus monkeys or hamsters. This newly-isolated herpeslike virus is apparently not the cytomegalovirus of the guinea pig; but seems to exist as a latent infection in guinea pig strains.

1462 STRUCTURAL PROTEINS OF HERPES SIMPLEX VIRUS. (E.) Robinson, D. J. (Scottish Horticult. Res. Inst., Invergowrie, Dundee) and D. H. Watson. *J Gen Virol* 10(2):163-171, 1971.

A method for purification of herpes virus by means of fluorocarbon treatment, ultracentrifugation, sucrose gradient centrifugation and chromatography, and a description of the pattern of structural polypeptides of these purified preparations is reported. Preliminary stages achieved 50-fold concentration, 10-fold purification and 10-20% recovery of virus particles. Under the conditions of growth, 5-10% of the original yield of virus particles possessed envelopes and the concentrated virus obtained by ultracentrifugation had a protein content of $3.9 \mu\text{g}/10^{10}$ particles. The final preparation was virtually free of diffusible antigens which gave no lines in immunodiffusion tests using antisera either against cells infected with herpes virus or against uninfected cells; the particle/infectivity ratio of purified virus was 3-6 times greater than that for the crude virus. Samples of purified virus with labeled amino acids showed a complex band A containing about 50% of the recovered radioactivity and appeared to consist of at least 2 major components. The patterns obtained in polyacrylamide electrophoresis reflect the polypeptide composition of naked particles, suggesting that the nucleocapsids of herpes simplex virus are composed of at least 8 polypeptides.

1463 DIFFERENTIAL EFFECT OF 7,12-DIMETHYLBENZ-(a)ANTHRACENE ON INFECTIVITY OF HERPES SIMPLEX VIRUS TYPE 2. (E.) Docherty, J. J. (Milton

S. Hershey Med. Ctr., Pennsylvania St. U., Hershey), R. J. Goldberg and F. Rapp. *Proc Soc Exp Biol Med* 136(1):328-333, 1970.

The effect of incubation with 7,12-dimethylbenz(a)-anthracene (DMBA) on the infectivity of herpes simplex virus types 1 and 2 was investigated in cultures of rabbit kidney cells. Cells were infected with virus and incubated with DMBA in amounts of 10, 50 or 100 $\mu\text{g}/\text{ml}$ of culture. Virus titers obtained when the infected cells were incubated alone, with anthracene or with dimethylsulfoxide after 24 hr were comparable (titers of 5.0×10^5 plaque-forming U (PFU)/ml for cells incubated with anthracene and 1.9×10^6 PFU/ml for cells incubated with dimethylsulfoxide). Infected cells grown with DMBA showed markedly lower titers (1.3×10^4 PFU/ml after 24 hr). Incubation with DMBA in amounts of 100 or 50 $\mu\text{g}/\text{ml}$ reduced the infectivity of herpes simplex virus by 99%, while incubation with the other agents reduced infectivity 0-24%. The inactivation of virus by DMBA was found to be maximal when cells were incubated at 37°; herpes simplex virus type 2 was more susceptible to inactivation by DMBA at all temperatures than herpes simplex virus type 1; at 1°, DMBA reduced the infectivity of virus type 1 by 38%, while at the same temperature, DMBA incubation reduced the infectivity of virus type 2 by 61%.

1464 ACUTE LYMPHOCYTIC LEUKEMIA IN OWL MONKEYS INOCULATED WITH HERPESVIRUS SAIMIRI. (E.) Melendez, L. V. (Harvard Med. Sch., Southboro, Mass.), R. D. Hunt, M. D. Daniel, B. J. Blake and F. G. Garcia. *Science* 171(3976):1161-1163, 1971.

Peripheral blood changes characteristic of leukemia induced by herpesvirus saimiri inoculation (i.v., s.c., or intradermal) were studied in the owl monkey. Six animals died between 11 and 14 wk after the initial virus inoculation; 2 exhibited histopathological findings of malignant lymphoma accompanied by invasion of lymph nodes, spleen, liver, kidney and heart with lymphocytic cell types. Three animals exhibited hyperplasia of lymphocytes in lymph nodes with hepatic sinusoids containing excess numbers of lymphocytes; one animal with no signs of malignant lymphoma or lymphocytic hyperplasia died of an undetermined cause. Of 6 animals reinoculated in the 23rd wk, 4 died with gross and histopathological features of lymphocytic malignant lymphoma; 1 animal developed lymphocytic leukemia 1 wk prior to reinoculation; 2 developed leukemia with a total white cell count in excess of $90,000/\text{ml}^3$ 3 wk and 1 wk post-reinoculation, resp. Two animals killed at 36 wk showed no lesions. The incidence of malignant lymphoma in this study was 50% compared with 100% of all owl monkeys inoculated in earlier studies, with the course of the disease extending to 36 wk compared to prior survival times of 4 wk with the use of dilute inoculum. Variation in virus virulence or host variation may influence the pathogenicity of herpesvirus saimiri in the animal.

1465 ULTRASTRUCTURAL STUDIES OF A HERPESVIRUS OF TURKEYS ANTIGENICALLY RELATED TO MAREK'S DISEASE VIRUS. (E.) Nazerian, K. (ARS Reg. Poultry

Res. Lab., East Lansing, Mich.), L. F. Lee, R. L. Witter and B. R. Burmester. *Virology* 43(2):442-452, 1971.

Electron microscopic observation of duck embryo fibroblasts, chicken embryo fibroblasts, and chicken kidney cell cultures transformed by a herpesvirus of turkeys (HVT) showed HVT-transformed cell nuclei to contain large numbers of small (35 nm) hexagonal particles. The nuclear particles in HVT-transformed cells appeared in aggregates and occasionally took the form of crystals; in Marek's disease virus (MDV)-infected cells, particles were found singly when found at all and never appeared as crystals. In MDV-infected cells, particles were present only along with typical herpesvirions while in a few of the HVT-infected cells, the particles were seen in the absence of herpesvirions. HVT-infected cells contained crystalline arrays composed of particles having the size and electron density of ribosomes. Polykaryocytosis was found in both MDV- and HVT-infected cells; with infected duck embryos, the polykaryocytes were larger than those in the other cultures used. Nuclear inclusion bodies were more frequent in HVT- than in MDV-infected cells, but the bodies were similar and consisted of naked virions in both cases. The nucleocapsids of HVT- and MDV-infected cells were morphologically alike, having an electron-dense core; however, the nucleocapsids of the 2 virions differed in some morphological details. Certain nucleocapsids of HVT lacked the electron-dense core and contained several particles attached to the inner side of the capsid arranged in such a way as to give the viral core the form of an electronlucent cross. Envelopment of the nucleocapsid occurred in both HVT- and MDV-infected cells.

1466 INVESTIGATION OF ANTIGENIC RELATIONSHIP OF MAREK'S DISEASE, HERPES VIRUS AND EB VIRUS (HERPES-TYPE VIRUS). (E.) Stevens, D. A. (U. Med. Ctr., Stanford, Cal.), S. D. Kottaridis and R. E. Luginbuhl. *J Comp Path* 81(1):137-140, 1971.

The possibility of cross-reactivity between Epstein-Barr virus (EBV) and the viral agent of Marek's disease in chickens (MDHV) was investigated; immunodiffusion and immunofluorescence tests were run with human anti-EBV serum and infected chicken or rabbit anti-infected chicken MDHV antiserum. Results of homologous immunofluorescence testing of human serum against EBV antigen and anti-MDHV serum against MDHV antigen were invariably positive; however no cross-reactivity between anti-EBV serum and MDHV antigen or between anti-MDHV serum and EBV antigen were observed. Results in immunodiffusion tests with EBV and MDHV infected cell antigens were essentially identical to the results of immunofluorescence tests: reactions were seen only in homologous tests. However, precipitating antibody was found in 1 test in 3 of 4 Marek's disease-infected birds to an antigen in the EBV preparation. Apparently, EBV and MDHV do not enter into antigenic cross-reactions, and do not share antigens.

1467 PATHOGENICITY AND ANTIGENICITY OF CLONES FROM STRAINS OF MAREK'S DISEASE VIRUS AND THE HERPESVIRUS OF TURKEYS. (E.) Purchase, H. G. (Anim. Sci. Res. Div., Agric. Res. Serv., East Lansing, Mich.), B. R. Burmester and C. H. Cunningham. *Infect Immun* 3(2):295-303, 1971.

This paper describes the purification by cloning of three strains of Marek's disease virus and one of the herpesvirus of turkeys, their pathogenicity as observed in chickens, and their antigenicity as characterized by the use of indirect fluorescent-antibody and agar-gel precipitin tests. Of 50 attempts to filter viruses, 36% were successful with the herpesvirus of turkeys and showed a maximum number of 250 plaques as compared to 9 to 20 plaques for Marek's disease virus. Of the Marek's disease virus strains studied, the JM19 clone killed about 80% and the JMHP clone killed 0% of the chickens, and they induced 90 and 0% lesions, resp. Strains GA and RPL39 produced intermediate levels of mortality and a higher incidence of visceral lesions, while the herpesvirus of turkeys was nonpathogenic. All clones, including the herpesvirus of turkeys, contained the B antigen; JM19, JM34, JM35, JM36, RPL39 and GA gave evidence of A and other antigens while clones JM30, JM31, and JMHP lacked the A antigen. In plaques produced by clones with A antigen, a diffuse antigen in the cytoplasm of infected, morphologically normal cells surrounded the plaques stained with homologous antiserum. Herpesvirus of turkeys and Marek's disease virus can be distinguished by differences in intensity and distribution of staining antigen.

1468 EVALUATION OF THE CHICKEN IMMUNE RESPONSE TO MAREK'S DISEASE HERPESVIRUS. (E.) Zacharia, T. P. (Rockefeller U., New York, N. Y.). *J Reticuloendothel Soc* 9(2):138-146, 1971.

The immune response to sheep red blood cells of chickens infected with Marek's disease herpes virus was investigated. Chickens were infected with the virus various ages up to 6 wk; thereafter, sera were extracted and absorbed with 0.1 ml of sheep red blood cells and antigenic reactions were noted. There was a high correlation between the incidence of virus-associated gonadal and dorsal root ganglia tumors and elevated anti-virus antibody titers. In chickens exposed naturally or parenterally to virus the reciprocal mode hemagglutinin titer was 128. The immunocompetence of the herpes virus-infected chickens inoculated at 6 wk-of-age with sheep red blood cells was not depressed, and anti-virus antibody titers had modes of 6 (\log_2 titer) in this group; inoculated virus-infected and control chickens not exposed to virus had reciprocal mode titers of 64 and 128, resp. The anamnestic response to sheep red blood cell antigens was not depressed in virus-infected birds; reciprocal mode titers of 512 and 256 were recorded for the virus-immunized and sheep red blood cell inoculated birds, and for sham-inoculated birds resp.

- 1469 IDENTIFICATION OF THE NUCLEIC ACID OF MOUSE MAMMARY TUMOR VIRUS (MTV) USING FLUORESCENCE MICROSCOPY. (E.) El-Fiky, S. M. (Med. Res. Inst. Alexandria, United Arab Republic), N. H. Sarkar and D. H. Moore. *Acta Histochem* 37(2): 323-329, 1970.

The specificity of the acridine orange staining technique used for identification of RNA of the mouse mammary tumor virus has been tested by fluorescence microscopy. Dried droplet preparations of concentrated virions of Rauscher murine leukemia, influenza, mammary tumor virus and nucleoids of mammary tumor virus fluoresced a flame-red in blue-violet light while smears of reovirus showed a yellow-green fluorescence, indicating a double-stranded RNA; vaccinia virus preparations showed brilliant apple-green fluorescence indicating also the presence of double-stranded DNA. After nuclease digestion (RNase, DNase) as well as digestion with 0.5% pepsin, no change in fluorescence of B particles was observed, but treatment with pepsin, trypsin and deoxyribonuclease resulted in pale orange fluorescence. After treatment with the proteolytic enzymes and ribonuclease, the B particles were readily susceptible to ribonuclease action and showed green fluorescence; following incubation either with pepsin or ribonuclease, the fluorescence was flame-red. Following staining with acridine orange, the nucleoid fraction of P particles gave flame-red fluorescence, while the membrane fraction fluoresced green. These results provide convincing evidence for the single-stranded nature of the mammary tumor virus RNA in confirmation of earlier reports.

- 1470 STUDIES ON THE MOUSE MAMMARY TUMOR AGENT (MTA): II. CYTOCHEMISTRY OF AMINOPEPTIDASE IN NORMAL MAMMARY GLAND OF C57BL, SPONTANEOUS AND VIRUS-INDUCED MAMMARY TUMORS IN R III AND C57BL MOUSE STRAINS, RESPECTIVELY, AND IN CELL LINES PRODUCING THE MAMMARY TUMOR VIRUS. (E.) El-Fiky, S. M. (Inst. Med. Res. Alexandria, Egypt, UAR). *Acta Histochem* 38(1):181-188, 1970.

Intracytoplasmic granules associated with aminopeptidase were found in normal mouse mammary epithelial cells and in cells of virus-induced and spontaneous mammary adenocarcinomas in mice. In normal mammary glands, granules were grouped in localized aggregates, while in tumor tissue, granules were evenly distributed in the cytoplasm. The granular reaction was found to be most intense in tumor cells from strain RIII mice, followed by C57BL virus-induced tumor cells, and C57BL normal mammary cells. A granular aminopeptidase reaction was also found for cells in culture; enzyme activity was at a higher level in cells producing the mammary tumor virus than in normal cells, suggesting that increased aminopeptidase activity was not a cell reaction but was that of the virus particles.

- 1471 MAMMARY TUMORS, PLAQUES, AND HYPERPLASTIC ALVEOLAR NODULES IN VARIOUS COMBINATIONS OF MOUSE INBRED STRAINS AND THE DIFFERENT LINES OF THE MAMMARY TUMOR VIRUS. (E.) Heston, W. E. (Natl.

Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and G. Vlahakis. *Int J Cancer* 7(1):141-148, 1971.

Mammary tumors were developed with frequencies ranging from less than 1 to 100% by each of the following inbred mouse strains: C3H, C3HfB, C3HfDD, C3H-A^{VY}, C3H-A^{VY}fB, DD, DDfB, DDfC3H, BALB/c BALB/cfDD, BALB/cfC3H, A(High), A(Low), AfB and C57BL. The highest incidence of mammary tumors was found in C3H-A^{VY} mice (100%), and the lowest incidence (less than 1%) in A(Low) and C57BL mice; BALB/cfC3H mice also had 100% mammary tumor incidence. Low tumor incidence was found for AfB mice (1%) and DDfB mice (4%). While BALB/c mice had a tumor incidence of only 20%, BALB/cfDD mice had a tumor incidence of 97%. DDfC3H and C3H mice developed mammary tumors at the youngest average age of 6.8 and 7.2 months, resp.; C3HfB and DDfB mice developed tumors at the highest average age, 18.8 and 19.5 months, resp. Mammary tumor virus antigen was found in all but 4 strains, DDfB, BALB/c, A(Low), and C3HfB. Mammary tumor viruses were found in the milk of 20/27 C3H mice and in 23/28 C3H-A^{VY} mice; no virus was found in milk of C57BL or AfB mice. Virus plaques were the result of DD or BALB/c genotypes and DD virus but not of C3H or A genotype or of C3H or A virus. Hyperplastic alveolar nodules were found in all mouse strains developing mammary tumors; the age at which they first appeared depended on the mouse strain and on the line of virus; nodules appeared at the age of 3 months in DD, C3H and C3HfDD mice.

- 1472 IMMUNOLOGICAL AND PATHOLOGICAL MANIFESTATIONS OF MURINE SARCOMA VIRUS (MOLONEY) INFECTIONS. (E.) Schlom, J. (Coll. Phys. Surg., Columbia U., New York, N.Y.), J. B. Moloney and V. Groupe. *Cancer Res* 30(12):2955-2961, 1970.

In a study of the pathological picture of Moloney murine sarcoma virus (MSV) infections in mice, an inverse relationship was found between latency of tumor development and dilution of MSV inoculum. MSV dilutions of 10^0 - 10^{-2} produced tumors in 100% of mice with latencies of 3.5-7.3 days for 50% tumor incidence (Y_{50}); dilutions of 10^{-3} produced tumors in 90% of mice with latency of 12.2 days for Y_{50} . In mice given virus dilutions of 10^0 - 10^{-3} , tumors regressed in 100-78% of cases after 14-21 days. Mice receiving a 10^0 virus dilution with regressed tumors showed relapse, usually resulting in death, in 40% of cases, while the relapse percentage in mice given 10^{-1} to 10^{-3} virus dilutions was 56% and 43%, resp. The tumors developed rapidly in the left inguinal region injection site, and were characterized as rhabdomyosarcomas; hepatic tumors were also observed. Adult mice susceptible to MSV tumor induction displayed levels of antibody to MSV sufficient to neutralize more than a $10^{3.2}$ median effective dose of virus. Antibody titers were not dependent on initial MSV dose, but increased with increasing duration of tumor before regression. Relapse of mice with regressed tumors was marked by pronounced growth in the mesenchymal region surrounding the splenic follicles of cells which contained many mitotic figures and which were refractory to staining. Leukemoid reactions were also seen in livers examined during relapse. Relapse was also marked by the ap-

pearance of metastatic lesions. Mice immunized against MSV by inoculation of live MSV developed tumors in only 15% of cases following a challenge dose of virus potent enough to cause tumors in 100% of nonimmunized mice.

- 1473 A STUDY OF THE SENSITIVITY OF VARIOUS TISSUE CULTURES TO THE MOLONEY (MOUSE SARCOMA) VIRUS. (Rus.) Kukayn, R. A. (A. Kirkhenshteyn Inst. Microbiol. Riga, U.S.S.R.), L. I. Nagayeva, A. V. Zhilevich and S. D. Nitavskaya. *Vop Onkol* 16(12):31-37, 1970.

The interactions between the Moloney sarcoma virus (MSV) and tissue cell cultures from various animal species were explored in terms of cell morphology, mitotic rates and viral reproduction within the cell cultures. The SV-221 strain of MSV was passaged in BALB/c mice which were sacrificed 7-10 days after the appearance of a tumor; the tumor homogenate was used to infect tissue cultures of BALB/c AKR, C3H mouse embryo fibroblasts, Wistar rat embryo fibroblasts and kidney tissue, human embryo kidney tissue, Syrian hamster embryo fibroblasts and kidney tissue, calf embryo kidney, guinea pig and chicken embryo fibroblasts and transplantable L cells. The most striking morphological changes were noticed in the L cell cultures 24 hr following viral infection, where the regularly distributed polymorphic cells were substituted by a network-like pattern of lengthened cells; one day later round cells focused into islets and remained throughout the observation period. Morphological alterations were noticed mainly in cell cultures which appeared to be capable of supporting viral reproduction (rat embryo fibroblasts and human embryo kidney cells), except for the C3H mouse embryo fibroblasts where no viral reproduction occurred. Viral antigen was detected 2-3 days following infection in L cells, in BALB/c mouse embryo, Wistar rat embryo and Syrian hamster embryo fibroblasts, human embryo, hamster embryo and calf embryo kidney tissue cultures. Inoculation of BALB/c mice with infected cell culture material led to the development of rhabdomyosarcoma at the inoculation site within 7-15 days in 50-80% of the animals. Changes in mitotic activity exhibited no specific features due to the MSV infection. However, virus-induced chromosomal alterations focused in the centromeres, and metaphasic and anaphasic chromosomal retardation was ascertained; a decreased amount of diploid cells was noticed in 8 of the 10 cell cultures. MSV seemed to produce no effects on the rat embryo kidney tissue culture which was thus defined as "not sensitive" to MSV.

- 1474 RECOVERY OF MOLONEY MURINE SARCOMA VIRUS ADDED TO BOVINE MILK. (E.) Burger, C. L. (St. U. New York Upstate Med. Ctr., Syracuse), C. C. Chamberlain, M. C. Barstow and B. C. Maher. *J Nat Cancer Inst* 46(1):121-125, 1971.

Recovery of infectious Moloney murine sarcoma virus (MSV) from bovine milk was attempted through continuous flow centrifugation. Essentially all of the infectivity of the MSV added to the milk (1 g equivalent

of MSV to 50 ml skim milk) was recovered, regardless of whether direct pelleting or rebanding technique were employed. Past failure to detect an active virus agent responsible for bovine leukemia may have been due to inactivation before sampling or low titer of virus.

- 1475 THE PRESENCE OF DEFECTIVE VIRUS PARTICLES IN A MOLONEY SARCOMA VIRUS STRAIN PASSAGE (Rus.) Yakovleva, L. S. (Inst. Exper. and Clin. Oncol. Moscow, U.S.S.R.). *Vop Virusol* 15(6):708-711, 1970.

The titer of a Moloney sarcoma virus (MSV) strain, passaged in BALB/c mice at 18 day intervals and isolated from a tumor maintained in CC57Br mouse fibroblast culture, increased 2-4-fold by addition of a Mazurenko leukosis virus (MazLV) strain obtained from the spleen and lymph nodes of CC57Br mice with Mazurenko's leukosis. This increase in infective titer indicated the presence of defective virus particles (70%) within the studied MSV strain; these particles were able to induce sarcoma in mice only in the presence of the MazLV. The presence of defective MSV particles seemed to indicate that the infective titer of the virus may be subject to variations under natural conditions.

- 1476 STUDIES OF MURINE SARCOMA VIRUS: II. DETECTION OF GROUP-SPECIFIC ANTIGENS BY IMMUNOFLUORESCENCE. (E.) Chuat, J. C. (Hosp. St. Louis, Paris, France), F. Lasquellec, A. M. L'Hirondel and M. Boiron. *Int J Cancer* 7(1):101-111, 1971.

Mouse, rat and hamster cell lines infected with Moloney murine sarcoma virus were examined for the group specific antigen (GS) of the murine tumor virus using antisera prepared in rats bearing tumors induced by the Moloney virus. GS antigen was found in the cytoplasm of mouse and rat cells 15 hr after a single infecting dose. Antigen was also found in cell lines infected chronically with murine leukemia or sarcoma viruses, including Rauscher and Gross viruses. Antigenic reactions were found to be exclusively to GS antigens. Viral envelope antigens detectable initially were located at the cell membrane; their appearance and the appearance of GS antigens showed similar time courses. However, envelope antigenicity decreased as tumor cell lines were passaged on living animals. Two hamster cell lines transformed by Moloney virus were negative for GS antigen. Sera taken from hamsters bearing Moloney sarcoma virus-induced tumors failed to elicit a GS reaction in the hamster cells.

- 1477 FREUND ADJUVANT-STIMULATED DEVELOPMENT OF VIRAL RETICULOSARCOMATOSIS IN CC57BR/MV MICE. (Rus.) Ter-Grigorov, V. S. (P. A. Herzen Sci Res. Inst. Oncol. Moscow, U.S.S.R.), V. M. Bergolz and O. Ya. Moskovkina. *Vop Virusol* 15(6):717-721, 1970.

The effect of complete Freund's adjuvant (FA) on the development of Bergolz virus-induced reticulosis (RS) in CC57BR/MV mice was investigated. Inoculation with leukemogenic amounts of cell

free extracts from tumor nodules associated with A (0.1 ml i.p.) decreased 3-fold the latency period for the development of RS in 100% of the experimental animals. When 10^4 tumor cells and FA were inoculated i.p. 22 of 23 mice developed RS within 1 month while inoculation with RS tumor cells without FA induced RS in 17% of the animals 2 months after inoculation. When 5×10^5 RS cells were injected into mice i.p. 8 days after FA inoculation, 21 of 21 mice died of leukemia 2 wk later, and tumor invasion of the liver, spleen, thymus and lymph nodes was seen in 14 mice 21 days after the inoculation of RS cells. FA stimulation of RS development in CC57BR/MV mice appeared to involve an enhancement of RS virus multiplication induced by the administration of the adjuvant.

478 CONDITIONAL LETHAL MUTANTS OF AVIAN SARCOMA VIRUSES: I. PHYSIOLOGY OF *ts* 75 AND *ts* 149. (E.) Friis, R. R. (U. Washington Sch. Med., Seattle), K. Toyoshima and P. K. Vogt. *Virology* 43(2):375-380, 1971.

Physiological activity of 2 temperature-sensitive mutants of avian sarcoma virus were analyzed by means of complement-fixation and uridine labeling of viral RNA. The half-life for the viruses tested at 41° was 60 min, indicating inactivation kinetics indistinguishable from wild type viruses. Cells transformed by the mutants were only 10% as effective in establishing tumors compared to the tumor-producing ability of the wild type-transformed cells. Rates of heat inactivation, envelope antigenicity and host range were identical to the wild type. Reversion frequencies to wild types were 3×10^{-6} for *ts* 75 and 4×10^{-6} for *ts* 149. Uridine labeling indicated that *ts* 75 infected cells synthesized RNA at 41° in substantial amounts 96 hr after infection. Whether DNA synthesis needed for virus production and for transformation can occur at 41° remains to be investigated.

479 INACTIVATION OF AVIAN SARCOMA VIRUSES WITH UV LIGHT: A DIFFERENCE BETWEEN HELPER-DEPENDENT AND HELPER-INDEPENDENT STRAINS. (E.) Friis, R. R. (U. Washington Sch. Med., Seattle). *Virology* 43(2):521-523, 1971.

The difference in UV radiation target size between Bryan high-titer strain of Rous sarcoma virus and helper-independent avian sarcoma viruses was studied. The helper-independent avian sarcoma viruses were more rapidly inactivated than the helper-dependent Bryan strain showing a survival fraction after 4 min of less than 0.001 - 0.01 vs 0.01 - 0.1. The use of identical cell systems (chick or pheasant embryo fibroblasts) and the comparison of helper-dependent and helper-independent viruses of the same subgroup rules out the effects of the differences of host cells and differences in virus structural properties. The inactivation kinetics appear to reflect a real difference in the size of the genetic target between helper-dependent and helper-independent viruses.

1480 STUDIES ON INHIBITION OF VIRAL ONCOGENESIS: II. INHIBITORY EFFECT OF L-ASPARAGINASE, CLAM LIVER EXTRACT AND METHOTREXATE ON ROUS SARCOMA VIRUS FOCUS FORMATION. (E.) Li, C. P. (Div. Biol. Standards, Natl. Inst. Hlth., Bethesda, Md.), W. G. Jahnes and N. M. Tauraso. *Arch Ges Virusforsch* 32 (2/3):236-243, 1970.

When L-asparaginase was added to primary chick embryo cell cultures 2 hr before or after infection with Rous sarcoma virus (Schmidt-Ruppin strain), viral focus-formation was inhibited; concentrations of 0.2 U of L-asparaginase/ml medium added 2 hr after virus infection resulted in 17-37 foci/culture plate, while the same amount added 2 hr before infection resulted in 47 foci/plate compared to 81-128 foci/culture plate for controls. Concentrations of 0.5 U L-asparaginase resulted in 1-6 virus foci when added 2 hr after infection, and 3 foci when added 2 hr before virus. Clam liver extract, added to cultures 2 hr before or after infection with virus, also inhibited focus formation when the dose of clam liver extract exceeded 10 μ g%; high-multiplicity infections of virus also enhanced the inhibitory effect of clam liver extract. Methotrexate 10^{-5} - 10^{-7} M produced nearly complete focus-formation inhibition when added to cultures 1-2 hr before and up to 3 hr after virus.

1481 INVESTIGATIONS ON THE PRESENCE OF VIRAL PARTICLES IN ROUS TRANSFORMED HAMSTER CELL LINES. (Fr.) Gazzolo, L. (I.N.S.E.R.M., Lyon, France) and G. De-The. *Int J Cancer* 7(1):119-130, 1971.

The electron microscopic examination of 9 hamster cell lines transformed *in vivo* and *in vitro* by Rous sarcoma virus (RSV) is described. The production of RSV by the transformed cells appeared to differ fundamentally in chick cells and in mammalian cells. All the transformed chick cultures produced the virus, but the mammalian transformed cells generally did not produce RSV. The electron microscopic examination confirmed the absence of the viral type C particles in the 7 lines transformed *in vitro*. However, this type of particle was found in the RS₂-TH₂ issue of a tumor induced *in vivo* by *in vitro* transformed cells. The RS₂ cells used for the tumor graft did not produce C particles; those particles found in the RS₂-TH₂ line were morphologically similar to mouse leukemogenic virus. The particles associated with the cell mitochondria of the other line transformed *in vivo* (SR/Cl₂) were similar to intracytoplasmic particles of type A. Only this line of all the lines studied was non-virogenic, in spite of the fact that the cells produced the GS (group specific) antigen. Particles of type R were observed in all the lines.

1482 ISOLATION AND CHARACTERIZATION OF PROTEINS FROM ROUS SARCOMA VIRUS. (E.) Hung, P. P. (Abbott Lab., North Chicago, Ill.), H. L. Robinson and W. S. Robinson. *Virology* 43(1):251-266, 1971.

The number and structure of protein components in the Bryan high titer strain of Rous sarcoma virus

(RAV-1) were studied in chick embryo fibroblasts by means of isoelectric focusing in urea. Seven radioactive peaks with isoelectric points between 3.5 and 9.9 were noted which, upon further analysis, revealed a total of 8 ^{14}C -amino acid-labeled proteins with molecular weights between 14,000 and 96,000 daltons. Three glucosamine labeled components and a 4th glucosamine-labeled component devoid of radioactive amino acids were electrophoretically separated. High complement fixation titers and crossing precipitin lines were demonstrated by two components in agar gel diffusion with hamster anti-serum to avian-tumor virus group-specific antigen. One or more of the proteins could be related to RNase and ATPase.

1483 BEHAVIOR OF CHICK EMBRYO CELLS IN TISSUE CULTURE WHEN INFECTED WITH ROUS SARCOMA VIRUS: I. LOSS OF CONTACT INHIBITION. (E.)

Levinson, W. (Dept. Microbiol., U. California, San Francisco), D. Heilbron and J. Jackson. *J Nat Cancer Inst* 46(2):323-335, 1971.

Contact inhibition was studied in chick embryo cells in tissue culture infected with Rous Sarcoma virus. The estimated mean coefficients of contact inhibition ratios (maximum inhibition = 0) for primary and secondary cell culture infected plates were consistently larger for initial cell concentrations of 2×10^5 or above at 36 hr or more of incubation; increasing the number of cells to as high as 8×10^5 per plate did not decrease the interval below 36 hr. On agar-containing medium, no significant difference in contact inhibition ratios occurred at 24 hr after infection, but at 48 hr the difference was significant at $P < 0.005$. When uninfected cell cultures were counted at 24 hr, the ratios increased from 0.09 with 2×10^5 cells to 0.33 with 8×10^5 cells; with increased incubation time, ratios for 2×10^5 cells increased from 0.09 at 24 hr to 0.44 at 72 hr, indicating that the degree of contact inhibition depends not only on cell density but also on the time of incubation, providing the medium remains unchanged. Infected plates tended to show more variability of number of nuclei than uninfected plates but the increased variability was apparently not related to any of the factors pertaining to experimental conditions.

1484 GLIOMAS INDUCED BY ROUS SARCOMA VIRUS IN THE DOG: AN ULTRASTRUCTURAL STUDY. (E.)

Haguenau, F. (Lab. Exp. Med., Coll. France, Paris), G. F. Rabotti, G. Lyon and A. Morailon. *J Nat Cancer Inst* 46(3):539-559, 1971.

Electron microscopy confirmed that gliomas induced in dogs by intracerebral inoculation of Rous sarcoma virus of the Schmidt-Ruppin strain were subependymal astrocytomas in 21 of 22 animals. The astrocytomas were of the type designated as spongioblastomas or pilocytic astrocytomas. The gliomas were often located in the left ventricle, though the viral inoculation had been on the right hemisphere; tumors occasionally invaded the hemispheres, and protruded into the lumen of the lateral ventricles. The main proliferating cell type of these gliomas had a clear

nucleus, a convoluted plasma membrane, filamentous cytoplasm and unusually small mitochondria. Crystal line arrays of filamentous material were seen in the cisternae of the ergastoplasm; these inclusions were not found in astrocytes, but they were often found in endothelial cells, and their significance was unknown. These crystalline aggregates may have been artefacts of viral infection in the cells. However, no virus particles were found in any of the glioma cells.

1485 SIZE DIFFERENCES AMONG THE HIGH MOLECULAR WEIGHT RNA'S OF AVIAN TUMOR VIRUSES. (E.)

Bolognesi, D. P. (Max Planck Inst. Virus Res., Tübingen, Germany) and T. Graf. *Virology* 43(1):214-222, 1971.

Sedimentation behavior of high molecular wt RNAs from avian tumor viruses (Rous sarcoma virus, Rous-associated virus and avian myeloblastosis virus strains) was studied by means of gel electrophoresis and sucrose gradient sedimentation analyses. Sedimentation properties revealed 3 high molecular wt RNAs designated as large (SRV-1), medium (MAV-BO), and small (SRV-H) molecules. In acrylamide-agarose gel separation a linear relationship was obtained with RNAs having a molecular wt below 2×10^6 daltons. A 6% difference in sedimentation in sucrose gradient between large and small molecules was noted, which represents a rather large portion of nucleic acid. Size differences were not directly related to its ability to produce tumors in mammals.

1486 PRESENCE OF VIRAL GENOME IN CHINESE HAMSTER EMBRYONIC CELL TRANSFORMED *IN VITRO* WITH BRYAN STRAIN OF ROUS SARCOMA VIRUS (B-RSV).

(E.) Hlozaneck, I. (Inst. Exp. Biol. Genet., Prague Czechoslovakia). *Progr Immunobiol Stand* 3:53-56, 1969.

Chinese hamster embryo cells cultured with Rous chicken sarcoma virus (Bryan strain) resulted in the transformation of the infected hamster cells within 6-8 wk. Transformed hamster cells did not produce tumors when inoculated into neonatal hamsters, but inoculated chickens developed typical Rous sarcomas which could be passaged as cell suspensions in chickens. Attempts to transfer sarcomas by a cell-free filtrate, however, did not induce tumors in recipients; preparations from the chicken sarcomas did not produce virus either. However, when chicken tumor cultures were superinfected with Rous associated helper virus, the non-productive cultures produced infectious virus.

1487 IDENTIFICATION OF VIRUS-SPECIFIC RNA IN CELLS INFECTED WITH ROUS SARCOMA VIRUS.

(E.) Garapin, A. C. (Dept. Microbiol., U. California San Francisco), J. Leong, L. Fanshier, W. E. Levinson and J. M. Bishop. *Biochem Biophys Res Commun* 42(5) 919-925, 1971.

RNA containing nucleotide sequences identical to those of the Rous sarcoma virus genome were identified in cytoplasmic and nuclear fractions of virus-infected and transformed cells. Equilibrium centri-

fugation on Cs₂SO₄ gradients showed that virus-specific DNA could anneal to RNA extracted from infected cells; virus-specific RNA was found in both cytoplasm and nuclei. No DNA:RNA hybrids were formed if either the DNA was incubated with RNA from uninfected cells or if a mixture of enzymatic product and RNA from uninfected cells was analyzed in Cs₂SO₄ without prior incubation at 37°. The DNA:RNA hybridization appeared to be specific, and the presence of DNA at the density of RNA was not merely fortuitous. The RNA containing nucleotide sequences similar to those of the viral genome comprised approximately 0.5% of the total RNA extracted from virus-infected cells. It was also possible to detect the DNA:RNA hybrids using a step-wise elution from hydroxyapatite.

- 1488 SOME PROBLEMS OF DETECTION OF GENOME OF ROUS SARCOMA VIRUS IN HETEROLOGOUS CELLS. (E.) Simkovic, D. (Cancer Res. Inst., Bratislava, Czechoslovakia) and B. Adamcova. *Progr Immunobiol Stand* 3:49-52, 1969.

Tumorigenicity of 3 rat tumor cell lines transformed by avian tumor viruses was investigated in chicks and rats; the tumor cell lines were rat embryo cells transformed *in vitro* by Rous sarcoma virus (TWERC), rat tumor cells induced *in vivo* by Rous sarcoma virus and maintained in cell culture for 5 yr (XCtc), and rat tumor cells transformed by Bratislava 77 virus (17/RBI/77). All 3 tumor cell lines induced rapidly growing sarcomas in newborn rats even at the low dose of 10³ cells/rat. Living TWERC cells injected into chicks failed to produce tumors; however, XCtc and 17/RBI/77 cells produced tumors in 11/27 and 14/18 chicks, resp. When disintegrated cells or cell free culture fluid was injected, only the 17/RBI/77 cells were tumorigenic. These results suggested that rat tumor cells transformed by avian tumor viruses may contain the viral genome in 3 different states: virus-producing (e.g., 17/RBI/77), virogenic (e.g., XCtc), and non-virogenic (e.g., TWERC). TWERC and XCtc cells contained the same tumor-specific transplantation antigens, but 17/RBI/77 cells did not show tumor specific transplantation antigen.

- 1489 INACTIVATION OF THE TRANSFORMING CAPACITY OF SV40 AND THE ONCOGENICITY OF ADENOVIRUS 12 BY ULTRAVIOLET IRRADIATION. (E.) Yamamoto, H. (Nat'l. Inst. Hlth., Tokyo, Japan). *Jap J Microbiol* 14(6):487-493, 1970.

Results of ultra-violet inactivation of simian virus 40 (SV40) and adenovirus 12 (Ad 12) on the transforming capacity of SV40 and the oncogenic capacity of Ad 12 were studied in baby mouse (C3H/He) brain tissue which was minced and grown in 10% calf serum and in hamsters, resp. The transforming capacity of SV40 was about 4 times more resistant to UV-inactivation than its infectivity; the percentage of survivals in plaque-forming units and focus-forming units relative to unirradiated controls were approximately 2-3% and 50%, resp., after 8 min of irradiation. Changes in the tumor-producing capacity of

Ad 12 by UV irradiation showed that unirradiated virus produced tumors in 2 out of 13 hamsters, whereas treated virus failed to produce any tumors in 8 hamsters. T antigen was positive in all smeared preparations of tumor cells. The enhancement of tumor induction by irradiation was not observed in the incidence of tumors or in the time of appearance of tumors. The capacity of adenovirus 12 to produce tumors was more resistant to ultraviolet-inactivation than its infectivity.

- 1490 VIRAL SUSCEPTIBILITY OF SV40 VIRUS TRANSFORMED HUMAN, BOVINE AND HAMSTER CELL CULTURES. (E.) Sahnazarov, N. (St. Nicolau Inst. Virol., Bucharest, Rumania), M. Nachtigal, N. Cajal, L. H. Graffe and S. Ionescu-Homoriceanu. *Rev Roum Infra-microbiol* 7(4):311-317, 1970.

The susceptibility to viral infection of human embryo fibroblast and lung, golden hamster and bovine cell cultures transformed *in vivo* and *in vitro* by SV40 virus was studied. In human cell cultures herpes simplex virus multiplied in transformed lung tissue by the 25th wk after inoculation and produced titers similar to those obtained in normal embryo cell cultures. Bovine cell cultures, tested 21 wk after inoculation with herpes simplex, showed a limited multiplication and gave a titer of 1.5-2.5 log lower than that obtained in the non-transformed cell culture, whereas hamster cell cultures, in the course of a 16-day observation period, revealed no cytopathic alterations in response to enteroviral infection. These cultures, however, were susceptible to parainfluenza virus type 3 and vaccinia virus. Infection with herpes simplex virus was seen in chemically induced tumors which offered a substrate with a marked susceptibility to infection with herpes simplex virus. The incomplete cytopathic effect obtained in hamster cell lines inoculated with herpes simplex virus might be attributed to a mixture of cells some of which are susceptible and some of which are resistant to the infective agent.

- 1491 NUCLEOLAR CHANGES ACCOMPANYING THE *IN VITRO* TRANSFORMATION OF HAMSTER AND BOVINE CELLS INDUCED BY SV-40 VIRUS. (E.) Mironescu, S. (C. I. Parhon Inst. Endocr., Bucharest, Rumania), N. Sahnazarov and M. Nachtigal. *Rev Roum Infra-microbiol* 7(4):279-294, 1970.

The SV40-induced transformation of adult golden hamster kidney, newborn golden hamster lung and fetal bovine kidney cell cultures was studied microscopically for nucleolar changes. After an initial decrease, the titer of replicating SV40 in primary cultures of hamster embryo cells was seen to increase slightly and then decrease after 96 hr. Morphological changes seen 140 days after inoculation revealed abnormally lobulated nuclei, the incidence of which decreased thereafter. Mitosis gradually increased with time in newborn hamster lung cultures following inoculation with SV40 but decreased progressively in all other tissue studied. Hamster kidney cell cultures exhibited a biphasic curve with respect to mitotic abnormalities, whereas in the new-born ham-

ster lung cultures a progressive decrease in incidence of abnormal anaphases and telophases occurred to below control levels; bovine kidney cell cultures showed no increase in mitotic abnormalities during the first 15 wk after inoculation but thereafter showed an increasing incidence of abnormalities in both phases. Gradual decreases in nucleolar size toward the end of the observation period were observed with the mean number of nucleoli per nucleus showing striking changes in all cultures; "aniso" nucleoli appeared 60 days after viral infection. S.c. injection of tumor cells into unconditioned golden hamsters resulted in no detectable tumor masses up to 210 days after inoculation. The incidence of anisonucleoliosis closely parallels the increasing frequency of marker 1 chromosomes with both parameters attaining maximal values at about the same time.

- 1492 IDENTIFICATION AND PROPERTIES OF COMPLEX FORMS OF SV40 DNA ISOLATED FROM SV40-INFECTED AFRICAN GREEN MONKEY (BSC-1) CELLS. (E.) Rush, M. G. (New York U. Med. Sch., New York, N. Y.), R. Eason and J. Vinograd. *Biochim Biophys Acta* 228(3):585-594, 1971.

Identification of a complex viral DNA in monolayer cultures of African Green monkey kidney cells infected with simian virus 40 (SV40) is reported. The average circular duplex DNA yield from 50 dishes of confluent cells infected at a multiplicity of 2 PFU/cell and worked up 64 hr after infection was 600 µg DNA. Intracellular (SV40) DNA isolated 60 hr after infection contained about 1% each of catenated dimers and circular dimers with similar amounts of circular trimers. The latter were essentially unaffected by viral growth in the presence of 10 µg/ml ethidium bromide, which contrasts with the induction by this agent of large quantities of circular dimers in other organisms. At present neither the function nor the mechanism of formation of the multiple DNA forms is understood.

- 1493 STUDIES ON RESTRICTED GROWTH OF HERPES-VIRUSES IN SV40-TRANSFORMED CELL LINES. (E.) Geder, L. (Med. Sch. U. Debrecen, Hungary), L. Vaczi and E. Jeney. *Acta Virologica* 15(1):35-46, 1971.

Cultures of human and rodent cells, normal and SV40-transformed, were infected with herpes simplex virus obtained from human conjunctival and genital infections; of the SV40-transformed cells, SV40 production was inducible in 2 strains, which contained large amounts of tumor antigen and were highly oncogenic. Herpes simplex virus grew better in normal hamster fibroblasts and in a line of hamster tumor cells than in SV40-transformed hamster cells of high inducibility, oncogenicity and tumor-antigenicity. The latter cell lines, infected with herpes virus, showed a 1.5-2.5 log unit difference in intracellular, and a 0.5-1.72 log unit difference in extracellular virus titer compared to herpes virus grown in normal cells. Herpes virus obtained from conjunctival exudate produced higher virus titers in normal and in SV40-transformed hamster and human cells than the

herpes virus isolated from the genital lesion. In SV40-transformed human embryonic fibroblasts, the intra- or extracellular virus yields were about 10 times less at 6, 13 and 24 hr postinfection with herpes virus than in normal fibroblasts. Normal cells upon infection with herpes virus produced 8-16 times more complement-fixing antigen than did SV40-transformed cells. However, in normal and transformed cells treated with cytosine arabinoside, equal amounts of early herpes virus-specific soluble antigens were produced. The low yield of infectious herpes virus from SV40-transformed cultures was thought to be due to the presence of a small number of virus-producing cells; herpes virus-specific antigens were produced by transformed cells which did not produce infectious herpes virus. Human cytomegalovirus also grew much better in normal than in SV40-transformed human embryonic fibroblasts, the differences amounting to 2-3 log units.

- 1494 SUPERHELIX DENSITY HETEROGENEITY OF INTRACELLULAR SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID. (E.) Eason, R. (Dept. Biochem., U. Glasgow, Scotland) and J. Vinograd. *J Virol* 7(1):1-7, 1971.

The closed simian virus 40 (SV40) DNA species formed in the course of infection of African green monkey cells (BSC-1) with SV40 were examined by application of the density separation method. Closed DNA isolated 60-70 hr after infection consisted of intracellular DNA and viral DNA; the former banded at a higher density than the viral DNA whether treated with Pronase or extracted with sodium dodecyl sulfate, indicating a physical difference in the 2 sets of DNA molecules. In 7 experiments the banding distance between the nicked DNA and the intracellular DNA was 9-3% greater than the distance between the nicked DNA and the viral DNA. The band width at half-height of the intracellular DNA appeared to be 20% larger than the corresponding width for viral DNA; tests for superhelix density heterogeneity showed the intracellular closed DNA to be heterogeneous and to be 3/4 as large as the superhelix density of the viral DNA. Density and light fractions obtained from viral DNA isolated from purified SV40 showed superimposition of the bands and a constant normalized ratio of isotopes across the band, indicating homogeneity. Intracellular closed DNA obtained from ethidium bromide-treated cells mixed with closed intracellular DNA from untreated infected cells showed two overlapping non-superimposed bands; corresponding mixtures of the viral DNA species gave completely superimposable bands. The results indicate homogeneity of both the viral and intracellular DNA obtained from ethidium-bromide-treated cells.

- 1495 SV40 REPLICATION IN PRESENCE OF MONKEY KIDNEY ANTIBODIES. (E.) Bottiger, M. (Karolinska Inst., Stockholm, Sweden). *Progr Immunobiol Stand* 3:34-38, 1969.

Incubation of SV40-infected monkey kidney cells with poliovirus vaccine batches and monkey kidney cell antiserum produced a delay in the cytopathic effect associated with SV40 infection. No delay of cytopathic effect was seen when SV40 was grown in med-

containing normal horse, rabbit or calf sera. SV40 antibodies could not be found in rabbit or horse hyperimmune anti-polio sera. The cytopathic effect of anti-monkey kidney cell serum prepared in rabbits by injections of disrupted monkey kidney cells was tested by incubation of the serum with SV40, poliovirus type 1 (Chat strain) and poliovirus type 3; proportions of anti-monkey serum in the medium ranged from 1:16-1:128. At serum dilutions of 1:16, tube titration titers of SV40 were decreased to 1.5 log₁₀ TCID₅₀ at 10 days postinoculation compared to titers of 6.0 log₁₀ TCID₅₀ for SV40 titrated without anti-monkey serum in the medium. Lower concentrations of anti-monkey serum did not affect SV40 titers appreciably. The apparent toxic effect of the monkey kidney antibodies was reversible to some extent; with removal of the anti-monkey serum by change of medium after 2 hr of incubation, cell cultures regained their normal appearance and SV40 titers recovered. Cross reactions between anti-HeLa cell serum and monkey kidney cells was also observed.

1496 PROPERTIES OF ARGINASE FROM SV40-INDUCED HAMSTER FIBROSARCOMAS AND HAMSTER LIVER TISSUES. (E.) North, J. A. (Dept. Microbiol., Brigham Young U., Provo, Utah), G. Schwebach and J. H. Mangum. *J Nat Cancer Inst* 46(3):615-620, 1971.

Arginase activity was found to be 2-4 times higher in SV40-induced fibrosarcomas in hamsters than in normal hamster liver tissue; enzyme activity in fibrosarcomas ranged from 20-33 μ mole urea/mg/min, while enzyme activity in hamster liver amounted to less than 8 μ mole/mg/min. Two fractions containing arginase activity were obtained from both fibrosarcomas and normal liver by chromatography on CM-cellulose columns. One fraction was found to contain 82% of the total enzyme activity, the other 18%. The two fractions of each tissue exhibited similar Michaelis constants for arginine, as well as similar inhibitor constants for ornithine and canavanine although the Michaelis constant for arginine with arginase from hamster liver was about 3 times higher than that for the enzyme from fibrosarcoma tissue. The canavanine inhibition constant for fibrosarcoma tissue was larger than that for hamster liver tissue, while the ornithine inhibition constant was smaller in fibrosarcoma tissue than in hamster liver. The molecular wt of fractions I and II of arginase from hamster liver were found to be 140,000 and 95,000, resp. The molecular wt for fractions I and II of arginase from fibrosarcoma were, resp., 135,000 and 100,000.

1497 STRUCTURE OF SIMIAN VIRUS 40: V. LOCALIZATION OF THE C-TYPE POLYPEPTIDE CHAINS. (E.) Koch, M. A. (Max Planck Inst. Virus Res., Tübingen, Germany), H. Becht and F. A. Anderer. *Virology* 43(1):235-242, 1971.

The structure of simian virus 40 (SV40) and localization of the C-type polypeptide chains were studied utilizing hyperimmune sera from rabbits and convalescent sera from monkeys experimentally infected with the virus. Infectivity tests showed that the

complex of C polypeptides and the viral DNA did not infect cells with the same efficiency as an equivalent amount of complete virus. Serum from a rabbit immunized with C polypeptide gave a positive reaction with SV40 virions, and empty shells possessed the same reactivity as intact SV40. C polypeptides pretreated with a protease-free DNase had no neutralizing activity and reacted weakly or not at all with SV40 and C polypeptide in the complement fixation and indirect hemagglutination tests. Either greatly reduced immunogenicity or altered antigenic specificity of DNase-treated C polypeptides may explain these findings.

1498 THE *IN VITRO* EVOLUTION OF A GOLDEN HAMSTER LUNG CULTURE INFECTED WITH SV40 VIRUS. (E.) Sahnazarov, N. (St. S. Nicolau Inst. Virol., Bucharest, Rumania), M. Nachtigal, L. H. Graffe, S. Ionescu-Homoriceanu and N. Cajal. *Rev Roum Inframicrobiol* 7(4):319-325, 1970.

Alterations in newborn golden hamster lung cell cultures inoculated with simian virus 40 have been observed through co-cultivation with *Cercopithecus aethiops* kidney cells and direct and indirect staining methods. Subcultivation of the lung cell line at 7-10 day intervals resulted in a slow-forming monolayer of cell islets, nonconfluent and with frequent detritus and developing giant nuclei with increasing numbers of nucleoli in some cells after 55-58 days. Cultures stained with hematoxylin-eosin at different intervals showed a gradual increase in the epithelial component with epithelial predominance occurring after 337 days. The infective virus was present at 7 days after inoculation but was absent by day 26, and the tumoral antigen was not found in the nuclei at 362 days after inoculation; oncogenicity was not observed at 308 days after inoculation. Cytogenetic analysis of the lung cell culture at passage 2 showed that 26% of the cells had a diploid number of chromosomes, and 26% had a tendency toward hypotetraploidy. At passages 6 and 50, variation of the chromosome number tended toward tetradiploidy with later passages showing numerical increase in chromosomes. In its evolution towards a stable line, hamster lung cultures exhibit a particularly long stationary phase of 8-22 weeks.

1499 INDUCTION OF CELLULAR DNA SYNTHESIS BY SUPERCOILED SV40 DNA IN X-IRRADIATED MOUSE 3T3 CELLS. (E.) Rozenblatt, S. (Weizmann Inst. Sci., Rehovot, Israel) and E. Winocour. *Virology* 43(1):300-303, 1971.

DNA synthesis was induced in irradiated mouse cells by inoculating them with supercoiled DNA of SV40 (i. e., DNA component I). Mouse cells were given 5000 rads of X-irradiation to reduce background DNA synthesis prior to infection of the cells with viral DNA. Cell cultures were inoculated with 2×10^5 plaque-forming U of viral DNA. At 29-30 hr postinfection, the proportion of DNA-synthesizing cells in the cultures inoculated with SV40 DNA component I was 10-fold higher than that in the control cultures not inoculated with viral DNA. During the same time inter-

val, the incorporation of ^{14}C -labeled thymidine in the cultures inoculated with viral DNA was about 6-fold higher than in the control cultures. DNA-DNA hybridization experiments showed that the induced DNA synthesis was cellular rather than viral.

- 1500 DENSITY INHIBITION OF MOTILITY IN 3T3 FIBROBLASTS AND THEIR SV40 TRANSFORMANTS. (E.) Gail, M. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and C. W. Boone. *Exp Cell Res* 64(1):156-162, 1971.

Density inhibition of motility in cultures of mouse fibroblasts and SV40-transformed mouse fibroblasts was determined on observing position changes over time of selected cells. The motility constant was plotted for 3T3 mouse fibroblasts and virus-transformed mouse fibroblasts; the motility of normal fibroblasts changed little if at all over 24 hr. However, virus-transformed fibroblasts showed motility decreased by a factor of 8 over 24 hr. G, a measure of density inhibition of motility, was computed as $3.22 \mu\text{m}^2/\text{h-cell}$ for normal and $0.19 \mu\text{m}^2/\text{h-cell}$ for transformed cells. After change of culture nutrient medium, the motility of transformed cells was not changed appreciably, but the motility of normal cells decreased by a factor of 3 over 99 hr. This finding eliminated the depletion of a nutritional "locomotion factor" as an explanation for the observed decrease of normal fibroblast motility. Apparently, a strong density inhibition of motility in normal cells reflects a strong mutual adhesivity of these cells.

- 1501 CELLS, INTRACELLS AND SCHIZOGENY: I. SOME NEW LINES ESTABLISHED *IN VITRO* HAVING INTEREST IN CYTOBIOLOGY, CANCEROLOGY AND VIROLOGY. (E.) Valladares, Y. (Natl. Inst. Oncol., City U. Madrid, Spain) and Y. Alvarez. *Rev Esp Oncol* 16(1):23-45, 1969.

New cell lines of human, hamster and mouse origin have been developed through serial passage of "cancer-virus" (CV) and simian virus 40 (SV40) in cultures of embryo tissue from Syrian golden and albino hamsters and strains of SWR mice. A cell line from a CV-induced hamster sarcoma was established which was referred to as TC-CV/INO and produced sarcomas within 2 months after s.c. inoculation in all of 25 inoculated mice. An established line, designated as TC-SV40/INO, was produced from passing SV40 strain PA-57 in MkK cell-line from patas monkey; upon inoculation of LLC-MK₂ derived cell cultures with TC-SV40/INO, cytopathic effects which later disappeared were seen and the culture was maintained only by adding uninoculated LLC-MK₂ derived cells. Hamsters inoculated with TC-SV40/INO cells developed tumors that were evident after 37 days, and death occurred 5 wk after appearance of tumors and 10 wk after inoculation. Hamsters inoculated with TC-CV/INO cells developed tumors within 35-50 days which were smaller in size than those in mice; death occurred after several months. Cancervirus-inoculated mouse embryo cultures, known as ER-CV/INO, promoted tumors within 16 days after inoculation into mice, and

death occurred 19-41 days after the appearance of tumors which caused great skin distention and ulceration. Multi-nucleolated cells, large nucleolus, increased numbers of degenerated giant cells were constant features of all cell lines.

- 1502 THE UPTAKE OF SV40 DNA BY NONPERMISSIVE CELLS IN THE PRESENCE OF DEAE-DEXTRAN. (E.) Howard, B. V. (George Washington U. Sch. Med. Washington, D. C.), M. K. Estes and J. S. Pagano. *Biochim Biophys Acta* 228(1):105-116, 1971.

The uptake of tritiated DNA of SV40 by nonpermissive mouse cells in the presence of DEAE dextran (100 $\mu\text{g}/\text{ml}$) was 7-29% in 20 min after 3 washings. When DEAE dextran concentrations were varied and DNA and DEAE dextran were premixed, the initial attachment of ^3H -DNA to cells and the radioactivity associated with cells after 24 hr were maximal at DEAE-dextran concentrations of 100 $\mu\text{g}/\text{ml}$. When the cells were pre-treated with DEAE-dextran, the optimum uptake of ^3H -DNA was achieved with 3000 $\mu\text{g}/\text{ml}$ of DEAE-dextran. Incubation of cells and DEAE-dextran with concentrations of ^3H -DNA ranging from 10-50 $\mu\text{g}/\text{ml}$ did not affect the uptake of DNA. Both the initial attachment of ^3H -DNA and the amount of DNA associated with cells were maximal after 1 min of incubation; temperature of 5-42° did not affect initial ^3H -DNA uptake by cells; however, maximal 24 hr association of DNA with cells required temperatures of at least 25°. DNA became insensitive to deoxyribonuclease after 30 min of cell contact in the presence of DEAE-dextran. Most of the DNA taken up by the cells was eventually hydrolyzed and excreted from the cells, but a small fraction of the viral DNA (0.5%) was retained in the cell nuclei. The addition of 500 $\mu\text{g}/\text{ml}$ of calf thymus DNA to the cell-DEAE-dextran-DNA mixture did not affect uptake of tritiated DNA. When the infectivity of SV40 DNA was tested in African green monkey kidney cells, it was found that the infectivity of the viral DNA was maximal at DEAE-dextran concentrations of 1000 μg for cultures in which DNA and DEAE-dextran were premixed. Increasing concentrations of added calf thymus DNA decreased the infectivity of the viral DNA in the monkey cells. DEAE-dextran appears to facilitate both the function of the viral DNA with the host cell, and the entry of the viral DNA into the cell.

- 1503 ANALYSIS OF THE MOLECULAR FORMS OF SV40 VIRUS 40 DEOXYRIBONUCLEIC ACID SYNTHESIS IN CYCLOHEXIMIDE-TREATED CELL CULTURES. (E.) Kikuchi (Baylor Coll. Med., Houston, Tex.) and K. Nakajima. *J Virol* 7(1):87-94, 1971.

African green monkey kidney cell cultures were infected with SV40, and the SV40 DNA was labeled with thymidine; infected cultures were then treated with 25 $\mu\text{g}/\text{ml}$ cycloheximide to inhibit DNA synthesis. Viral DNA was extracted and analyzed by cesium chloride ethidium bromide equilibrium centrifugation to determine the forms of DNA produced by cycloheximide-treated virus. By 24-28 hr postinfection, it was found that about half of the labeled DNA produced by the virus was of light buoyant density (nicked circular or

ear DNA forms) and half was of heavy density (superhelical form DNA). By 36-40 hr postinfection, about 80% of the DNA was of heavy density, and about 14% was of light density. Heavy density DNA was found by analysis in velocity sedimentation in neutral sucrose gradients to consist of 70-93% superhelical DNA which sedimented at about 21S; light DNA was found to consist of 3 principal regions made up of nicked circular DNA which sedimented at varying rates of velocity. Cycloheximide treatment did not produce an increase in heavy density, superhelical or closed-circular form DNA. In pulse-chase experiments conducted with or without cycloheximide, radioactive label first appeared in nicked molecular forms of DNA which sedimented faster than open-circular viral DNA; eventually, radioactivity was chased into superhelical form DNA. Polynucleotide ligase concentrations appear to be adequate in cycloheximide-treated SV40-infected cultures and there is no increase in duplication errors causing formation of circular oligomeric forms of SV40 DNA.

1504 DEOXYRIBONUCLEIC ACID REPLICATION IN SIMIAN VIRUS 40-INFECTED CELLS: IV. TWO DIFFERENT REQUIREMENTS FOR PROTEIN SYNTHESIS DURING SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID REPLICATION. (E.) Kang, H. S. (Dept. Biochem., Princeton U., N. J.), T. B. Eshbach, D. A. White and A. J. Levine. *J Virol* 7(1):112-120, 1971.

When 10 µg of cycloheximide was added to monolayer cultures of African green monkey kidney cells which had been infected with SV40 large-plaque mutant virus, the synthesis of SV40-specific DNA was inhibited by 99% after 2 hr. Cycloheximide inhibited synthesis of both 25S (replicating) DNA and 21S (mature) DNA equally until 1 hr after treatment; thereafter, the ratio of 25S to 21S DNA increased from 0.3 to 1.0. The amount of 25S DNA synthesized in 1 hr increased from 25% in untreated virus-infected cells to 50% 3-4 hr after the addition of cycloheximide. Removal of cycloheximide from treated infected cultures allowed the return of viral DNA synthesis to normal levels within 3 hr; during recovery the ratio of 25S DNA to 21S DNA remained elevated. Protein synthesis appeared to be required for the conversion of 25S DNA to 21S DNA, as indicated by the accumulation of the former DNA during cycloheximide inhibition of DNA synthesis. The protein-requirement hypothesis was further confirmed by the finding that virus-infected protein-rich growing monkey kidney cells converted 25S DNA to 21S DNA with less delay than protein-poor resting cells; at 20 hr after the addition of an isotope label to cultures, infected growing cultures had produced 50% more DNA than resting cultures. Viral DNA replication was not affected by the incubation of cells with a temperature-sensitive SV40 coat protein mutation.

1505 SV40-TRANSFORMED PROSTATIC CARCINOMA IN THE HAMSTER: EFFECT OF HORMONAL MANIPULATION ON THE GROWTH RATE. (E.) Abdalla, A. M. (Roy. Victoria Hosp., Montreal, Quebec, Canada) and J. A. Oliver. *Cancer* 27(2):468-470, 1971.

The effect of hormonal stimulation on the growth of a virus-induced prostatic carcinoma was investigated

in the hamster. Hamsters of both sexes were given dorsal injections of 5-10 mg of SV40-transformed prostatic tumor tissue obtained from a male hamster. Hamsters were then given injections of estrogen (5 mg), androgen (20 mg), or a progestational agent (10 mg Depo-Provera. Maximum tumor growth was observed in untreated males, with tumors attaining a size of 55 cm³ in 28 wk. Female controls and hamsters given androgens showed similar patterns of tumor growth, while animals treated with estrogen showed depressed tumor growth (38 cm³ tumor volume in 28 wk). Tumor growth in hamsters given the progestational agent was drastically reduced; by 29 wk the tumor volume in this group was 4 cm³.

1506 BEHAVIOUR OF ENZYME SYSTEMS IN CERCOPI-
THECUS AND RHESUS KIDNEY CELLS IN CONSEQUENCE OF SV40 VIRUS ACTION. (E.) De Barbieri, A. (S. Belfanti Inst. Sieroter., Milan, Italy), G. C. Tassi, G. Giacometti and M. E. Scevola. *Progr Immunobiol Stand* 3:136-138, 1969.

The behavior of enzyme systems in monolayers of Cercopithecus and rhesus monkey kidney cells infected with SV40 was investigated. Cultures were inoculated with virus at multiplicities of 2 TCID₅₀/cell. A cytopathic effect was observable only 72 hr after inoculation in the rhesus monolayers; however, a cytopathic effect was observed in Cercopithecus cells 48 hr after virus inoculation. Oxidative enzyme systems were impaired by viral infection in both cell types, while glycolysis, the pentose phosphate cycle, hexokinase, glucose-6-phosphatase dehydrogenase and 6-phospho-D-gluconate oxidoreductase were increased. Transketolase and transaldolase showed oxidative shifts toward the production of ribose-5-phosphate. In Cercopithecus cells, proteolysis was markedly inhibited, while in rhesus cells it increased by 40% over uninfected cells. Glutamic dehydrogenase and amino acid oxidase increased sharply in Cercopithecus cells, but no such increase was seen in rhesus cells.

1507 HUMAN-MOUSE HYBRID CELL LINES AND SUSCEPTIBILITY TO SPECIES-SPECIFIC VIRUSES. (E.) Pollack, R. (Sch. Med., New York U., New York, N. Y.), J. Salas, R. Wang, T. Kusano and H. Green. *J Cell Physiol* 77(1):117-120, 1971.

The susceptibility to infection by species-specific viruses of a human-mouse hybrid cell line was investigated. Viruses tested were poliovirus, SV40, and adenovirus, for which human cells are permissive of infection and mouse cells are not, and polyoma virus, for which mouse cells are permissive and human cells are not. Human-mouse hybrid cells supported poliovirus infection and gave viral yields comparable to those of the respective human parental lines; hybrid cells containing lower numbers of human chromosomes failed to support poliovirus infection. The hybrid cells permitted infection by SV40 and synthesized tumor antigen with a frequency higher than that of the mouse parental line which also permitted infection by this virus. Hybrid cells supported infection by polyoma virus, producing viral yields comparable to those produced by mouse parent cell lines;

human parent lines were not susceptible to polyoma virus infection. While adenovirus did infect human parental cells, it failed to infect mouse parental cells or the hybrid cells.

- 1508 SV40 VIRUS TRANSFORMED PROSTATIC CARCINOMA IN THE HAMSTER: I. COMPARISONS OF LACTATE DEHYDROGENASE ISOENZYMES WITH HUMAN PROSTATIC CANCER. (E.) Abdalla, A. M. (Roy. Victoria Hosp., Montreal, Quebec, Canada) and J. A. Oliver. *Invest Urol* 8(4): 442-447, 1971.

The inhibitory effects of stilbestrol, medroxyprogesterone, hydrocortisone and testosterone on lactate dehydrogenase (LDH) isoenzymes in human prostatic carcinoma and in an SV40 transformed prostatic carcinoma in the hamster were investigated *in vitro*. LDH consisted of 5 isoenzymes numbered according to their electrophoretic mobility as LDH I-V. None of the drugs tested had any effect on the LDH isoenzymes of the hamster or human prostatic tumor except stilbestrol, which inhibited human LDH IV and V almost completely after incubation with 0.375 mg for 3 hr; LDH III was partially inhibited. The LDH isoenzymes of the SV40 virus-transformed hamster tumor appear to differ from those of the human counterpart, as far as the response to stilbestrol inhibition is concerned.

- 1509 STUDIES WITH SV40 - ADENO 7 HYBRID VIRUS. (E.) Vonka, V. (Res. Inst. Immunol., Prague, Czechoslovakia), L. Kutinova and H. Zavadova. *Progr Immunobiol Stand* 3:39-43, 1969.

The growth of the SV40-adenovirus 7 hybrid which exists in 2 forms, the true adenovirus 7 and the defective viral particles consisting of the incomplete SV40 genome enveloped in the adenovirus 7 capsid was studied in the human diploid cell strains LEP-12 and LEP-14 and in green monkey kidney cells (GMKC). Both forms grew well in these strains; in LEP cells, new adenoviruses were detected from 23-38 hr after inoculation of the hybrid virus; in monkey cells, the latent period was shorter, the rise in the titers of both components of the hybrid was more abrupt, and the final titers were higher than in the LEP cells. Infection of dog kidney cells or hamster embryo fibroblasts with the hybrid virus resulted in cell transformation; the transformed cells were virus-free. Hamster cells transformed by the virus were oncogenic for adult hamsters, and some of the tumor-bearing hamsters contained antibodies reacting with both the SV40 and the adenovirus 7 T antigens.

- 1510 SOME PROPERTIES OF POLYOMA VIRUS "T" AND "TUMOUR" ANTIGENS. (E.) Zembala, M. (Med. Acad. Cracow, Poland), W. Ptak and Z. Porwit-Bohr. *Z Immunitätsforsch* 141(1):27-36, 1970.

T antigens obtained from polyoma virus-infected mouse and hamster cells were examined and compared with polyoma virus-induced tumor complement-fixing antigens (PV-TCFA). Mouse embryo, mouse kidney, and

hamster kidney cells were inoculated with polyoma virus at doses of 100 TCID₅₀/cell, and antigens were prepared from infected cultures. Detectable amount of T antigen were found in infected cultures 8-12 hr after inoculation with virus (CF titers of about 2-4 log₂¹ for all cell systems studied). Maximum antigen titers were recorded 24-48 hr postinoculation and titers ranged from 16-32 log₂¹ for the various systems. After 48 hr postinoculation, there was a sharp decrease in T antigen synthesis; however, at day 16 postinoculation, hamster kidney cells resumed T antigen production. No differences in physicochemical properties and serological activity were observed between T antigen and TCFA antigen synthesized in tumor cells. The molecular wt of the proteins active in tests was over 3 x 10⁵ daltons and 1.1-1.5 x 10⁵ daltons. The antigen form with higher molecular weight was thought to be an RNA-protein complex.

- 1511 EFFECT OF PHLEOMYCIN ON POLYOMA VIRUS SYNTHESIS IN MOUSE EMBRYO CELLS. (E.) Iwata, A. (Div. Biol., Kansas St. U., Manhattan) and R. A. Consigli. *J Virol* 7(1):29-40, 1971.

When 25 µg of phleomycin was added to mouse embryo cells infected with polyoma virus at multiplicities of 6.2 x 10⁶-1.0 x 10⁸, synthesis of virus was inhibited in the infected cells. Phleomycin added 4 hr after virus infection produced 96% inhibition of virus synthesis; phleomycin added 30 hr postinfection resulted in a 61% inhibition. The treatment of cells with phleomycin did not affect RNA or protein synthesis by cells; however phleomycin inhibited DNA synthesis, especially in uninfected cells. Uninfected cells treated with phleomycin synthesize about one third as much DNA as infected cells treated with phleomycin. A polyoma virus DNA component and virus antigen occurred in the presence of phleomycin; complete and incomplete virus particles were also found in cultures treated with phleomycin. Synthesis of complete virus was more sensitive to phleomycin treatment than was the synthesis of virus particles. The DNA synthesized in infected phleomycin-treated cells was found to be salt-extractable, as was the DNA in untreated infected cells.

- 1512 EPITHELIAL ORIGIN OF POLYOMA SALIVARY GLAND TUMORS IN MICE: EVIDENCE BASED ON CHROMOSOME-MARKED CELLS. (E.) Dawe, C. J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), J. Whang Peng, W. D. Morgan, E. C. Hearon and T. Knutsen. *Science* 171(3969):394-397, 1971.

Identification of the tissue type of origin of polyoma virus-induced neoplasms of the submandibular gland of polyoma-free mice of strains C₃H/Bi and CBA/H- was studied using a T₆ chromosome-marker system with a trypsin technique for separating epithelium from mesenchyme of gland rudiment. In 8 consecutive primary tumors arising in reassembled, transplanted 4 arose in reassemblies of CBA/H-T₆T₆ epithelium C₃H/Bi mesenchyme and 4 in the reciprocal combination. Cytogenetic identification of 8 primary and 13 transplanted derivatives showed 110 out of 523 metaphase figures to be host cells on the basis of diploidy

a single T₆ chromosome. The remaining 413 were classified as tumor cells because the karyotype was that of one or the other of the donor of two tissue types re-assembled in transplants and the aneuploid condition of many cells. Fourteen of 186 primary tumor cell metaphases demonstrated aneuploidy whereas 89 out of 198 first and second generation metaphases were aneuploid. In the 1st transplant generation of a tumor arising from a reassembly of T₆T₆ epithelium with unmarked mesenchyme, 42 of 49 tumor cells were hyperdiploid containing 4 T₆ markers, and the remaining 7 contained 2 T₆ markers; in controls 4 of 30 tumor cells contained 4 T₆ markers and 26 cells had only 2 T₆ markers. Histologically all neoplasms at the sites of transplant of intact and reassembled glands were undistinguishable from tumors induced by polyoma virus in indigenous salivary glands. Although mesenchyme plays an essential role during neoplastic transformation, it does not contribute cells to neoplastic populations.

1513 INDUCTION OF MITOCHONDRIAL DNA SYNTHESIS BY POLYOMA VIRUS. (E.) Vesco, C. (Lab. Cell Biol., CNR, Rome, Italy) and C. Basilico. *Nature* 229(5283):336-338, 1971.

The effect of polyoma virus infection on extrachromosomal DNA synthesis was studied in 3R3 mouse cells using ³H-thymidine labeling. Mitochondrial DNA synthesis was increased to 4-6-fold in confluent infected cultures compared to uninfected cultures, while nuclear DNA synthesis increased 25-29-fold. Fractionation by CsCl-ethidium bromide centrifugation showed that most of the mitochondrial radioactivity was incorporated into twisted circular molecules of mitochondrial DNA. The increased rates of synthesis in virus-infected cells in both compartments were smaller than the rates observed in uninfected cultures in the exponential growth phase. The nuclear activity in uninfected cells was less than 2% of that in multiplying cells whereas mitochondrial activity proceeded at 20% the rate of exponentially growing cells, and this difference may be related to the different sensitivity of the 2 synthetic systems to virus infection.

1514 CONTROL OF GLYCOLIPID SYNTHESIS IN A CULTURED HAMSTER CELL LINE. (E.) Robbins, P. W. (Massachusetts Inst. Technol., Cambridge) and I. Macpherson. *Nature* 229(5286):569-570, 1971.

The effect of cell density and polyoma viral transformation on synthesis of glycolipids were studied in a cultured hamster cell line utilizing chromatography and autoradiography. Normal cells growing at the lower cell density ($5 \times 10^3 \text{ cm}^{-2}$) showed much less incorporation of labeled palmitate into ceramide trihexoside, galactosylgalactosylglucosyl ceramide, the aminoglycolipid, β -N-acetylgalactosylgalactosylgalactosylglucosyl ceramide and an unidentified ceramide than cells at a higher density ($5 \times 10^4 \text{ cm}^{-2}$), while virus-transformed cells showed normal synthesis of phospholipids, hematoside and ceramide dihexoside. These results suggest that the lack of complex glycolipids in transformed cells could simply be a reflection of the lack of normal contact inhibition and lack of growth restraint.

1515 ACTIVATION OF POLYOMA VIRUS GENOME IN POLYOMA TUMOR CELLS. (E.) Saito, M. (Sch. Hyg. Serv., Kitasato U., Tokyo, Japan), F. Taguchi, K. Hasegawa, Y. Yoshida and D. Nagaki. *Jap J Microbiol* 14(6):512-515, 1970.

Reinvestigation of the rescue of polyoma virus (PV) from 2 polyoma tumor cell lines, KIT-5/2 and KIT-20/W, using a cell fusion technique is reported. Embryo cells produced completely negative results for polyoma viral antigen synthesis and HA production. PV specific fluorescence was about 3-5% and 10-20% in the 2 respective cell lines compared to control cultures in which neither PV viral antigen synthesis nor HA production could be detected throughout the experiments. Antigen was synthesized in infected kidney cell nuclei and reacted only with anti-PV virion antiserum; it did not react with anti-HVJ, anti-SV40 antiserum or normal rabbit serum. Differences in the PV activation pattern in the two cell lines may be either in the proportion of reactive tumor cells, the number of viral genome per cell or the status of the viral genome in the tumor cell.

1516 TRITIATED THYMIDINE INCORPORATION IN WARTS, KERATIC PAPILLOMAS AND EPIDERMODYSPLASIA VERRUFORMIS. (Fr.) Delescluse, C. (A. de Rothschild Ophthalmol. Found., Paris, France), M. Prunieras, M. Regnier, J. Arouete and C. Grupper. *Arch Derm Syph* 97(5-6):525-533, 1970.

1517 FORMATION OF SV40 IN HETEROKARYONS RESULTING FROM HYBRIDIZATION OF SENSITIVE AND TRANSFORMED CELLS EXPOSED TO UV IRRADIATION. (It.) Monti-Bragadin, C. (Inst. Microbiol., U. Padua, Italy), L. Conventi and G. A. Meloni. *Boll Soc Ital Biol Sper* 46(12):565-569, 1970.

- 1519 INTERFERON INDUCTION IN HAMSTER EMBRYO CELLS AND NEWBORN HAMSTERS INFECTED WITH POLYOMA VIRUS. (E.) Gotlieb-Stematsky, T. (Virus Lab., U. Tel-Aviv, Israel) and A. Vansover. *Arch Ges Virusforsch* 32(2-3):201-208, 1970.

Hamster embryo fibroblast cultures and 1 day old hamsters were infected at varying multiplicities with either of 2 strains of polyoma virus, strain C⁻H⁺ (a highly oncogenic strain) and strain C⁺H⁰ (a mildly oncogenic strain). Interferon was found to be produced in greater amounts by the C⁻H⁺ virus in fibroblast cultures than by the C⁺H⁰ virus; by 10 days postinfection the titer of interferon produced by C⁻H⁺ was 32, while that produced by C⁺H⁰ was 4. Interferon activity in culture was found to be sensitive to heating at 60°, and was lost by digesting cultures with trypsin. Treatment with antipolyoma virus serum did not impair interferon activity; interferon from hamster cells did not affect mouse embryo cells. C⁻H⁺ virus also produced higher titers of interferon in hamsters *in vivo* than did C⁺H⁰ virus; at 28 days after inoculation with C⁻H⁺, hamster internal organ extracts at dilutions of 1:32 showed 32% interference inhibition of challenge vesicular stomatitis virus, while extracts from hamsters given C⁺H⁰ showed zero interference inhibition. The peaks of interferon production were attained at the times when viral multiplication diminished in the hamster organs and when tumors began to appear. While C⁺H⁰ infection did not produce infectious virus, the C⁻H⁺ infection produced 10^{4.5} TCD₅₀ of virus/ml of organ suspension within 7 days after inoculation. HI antibody titers to the C⁻H⁺ variant were high by the second wk after infection; HI antibodies were not found in hamsters infected by the C⁺H⁰ variant. Interferon may have a role in tumor induction.

- 1520 IMMUNE RESPONSE TO GROSS VIRUS-INDUCED LYMPHOMA: I. KINETICS OF CYTOTOXIC ANTIBODY RESPONSE. (E.) Herberman, R. B. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and M. E. Oren. *J Nat Cancer Inst.* 46(2):391-396, 1971.

Male rats inoculated s.c. with cells from murine leukemias induced by Gross leukemia virus developed small tumors which regressed in 10-14 days in 65% of the cases; the remaining rats developed tumors which persisted for about 45 days before regressing. In rats with quickly-regressing tumors, the cytotoxic antibody response was found to describe a bimodal curve, with an early peak of mean antibody titer of 75 at 10 days postinoculation, and a second peak of mean titer of 650 at 30-40 days postinoculation. In the group of rats with more tenacious tumors, the first antibody peak occurred at 10 days postinoculation with a mean titer of 80; the second peak had a mean antibody titer of 820 and lasted from day 35-60 postinoculation. The height of the second antibody-titer peak in rats with enduring tumors was related to the size of the tumor-cell inoculum; large numbers of tumor cells elicited high titers of cytotoxic antibody. Rats given 1 x 10⁵ tumor cells developed mean antibody titers of 33, while rats given 5 x 10⁸ tumor cells developed antibody titers of 1280. Inoculation of a

second dose of tumor cells resulted in an increase antibody titers and the high titers persisted for 2 wk beyond the limit for control rats not given a second dose of cells. When antisera containing high titers of antibodies were fractionated on Sephadex G-200, the antibodies in initial-peak sera found to be 19S, and those in the second antibody titer peak were 7S.

- 1521 DIFFERENTIATION BY IMMUNOFERRITIN OF HERPES SIMPLEX VIRION ANTIGENS WITH THE OF RABBIT 7S AND 19S ANTIBODIES FROM EARLY (7-DAY) AND LATE (7-WEEK) IMMUNE SERA. (E.) Miyamoto, K. (Flow Lab., Rockville, Md.), C. Morgan, K. C. Hsu and B. Hampar. *J Nat Cancer Inst* 46(3):629-646, 1971.

Monolayer cultures of hamster kidney cells were infected with herpes simplex virus (HSV), and the interaction of the cells with HSV antibodies was studied. HSV antisera prepared in rabbits and fractionated by gel filtration into 7S and 19S fractions were separated into early and late antibodies, conjugated with ferritin and adsorbed with virus-infected hamster kidney cells. Before any virus appeared in the infected cultures, antigens which reacted with early 7S and 19S viral antibodies were found in the cytoplasm of infected cells and their nuclei, but most antigens which reacted with the late antibodies were found in nuclei only. Two hr after virus infection, ferritin-conjugated early 7S antibodies tagged small scattered aggregates of antigens in the cytoplasm. Large aggregates of antigens were found near the cell membrane or the nucleus 2-17 hr postinfection; these antigens reacted only with early 7S and 19S antibodies. There was evidence that disrupted nucleoli reacted with early 7S antibodies in the early stages of infection. Cytoplasmic antigens were thought to enter the nucleus through nuclear pores. In the nucleus, viral core of low density reacted with early 7S antibodies, while viral capsids reacted with both early 19S and late antibodies. Viral capsids were seen to be enveloped at the nuclear and tubular cytoplasmic membranes, the early stages of envelopment were marked by the appearance of "early" membrane-associated antigens which reacted with early 7S and late 19S antibodies. As envelopment progressed, the early membrane-associated antigens disappeared and antigens which reacted with early 19S and late 7S antibodies appeared. The antigenic sites on the viral capsid surface and envelope may differ in specificity for early 19S and late 7S antibodies.

- 1522 IMMUNOLOGIC MECHANISMS IN THE INDUCTION REGRESSION OF SHOPE PAPILLOMA VIRUS-INDUCED DERMAL PAPILLOMAS OF RATS. (E.) Kreider, J. W. (Med., Pennsylvania St. U., Hershey), S. A. Benjamin, Pruchnic and C. V. Strimlan. *J Invest Derm* 56(2):1971.

The effect of immunosuppressive therapy on the development and growth of epidermal papillomas induced by Shope papilloma virus was investigated in Lewis strain rats. Rats, which are normally resistant to Shope virus

induction, were treated with methylprednisolone (MP) or anti-rat lymphocyte serum, alone or together with thymectomy. The development and regression of tumors induced in MP-treated animals by grafts of virus-infected fetal rat tissue were observed. The incidence of papilloma development was increased 16-25% only by high (1.0 or 10.0 mg) doses of MP, compared to 0-8% in untreated controls. In untreated rats, papillomas regressed within 2 wk of appearance, while in MP-treated rats, tumors persisted until autopsy (6-8 wk). While mononuclear cell infiltration was observed to accompany tumor regression in controls, little infiltration was seen in rats treated with MP. The incidence of papilloma development in anti-lymphocyte serum-treated rats was not increased compared to untreated controls, nor did thymectomy affect the development of papillomas in rats given anti-lymphocyte serum. However, papillomas which developed in anti-lymphocyte serum-treated rats persisted to autopsy. An immunological mechanism apparently operates to cause papilloma regression in rats, while other factors seem to be involved in the original development of tumors.

- 1523 STUDY OF THE GROSS ANTIGEN IN BALB LEUKEMIAS AND TUMORS OF DIFFERENT ORIGIN.
(E.) Saal, F. (Natl. Acad. Med., Buenos Aires, Argentina), C. D. Pasqualini and S. L. Rabasa. *Cancer Res* 31(1):23-26, 1971.

Leukemias and other tumors of differing origins in BALB mice were investigated to detect the presence of Gross virus antigen (G). Leukemias were induced in the test mice by implantation of spontaneous leukemia cells from AKR mice and by implantation of tumor tissue induced by X-rays, ³²P, sarcoma 180, human leukemia tissue, and murine lymphoma tissue. All of the leukemias induced in BALB mice, whatever their origin, were G-negative when tested by the direct cytotoxic test. However, with the more sensitive indirect cytotoxic test or with typing by absorption, all leukemias and tumors of the BALB strain proved to be G-positive with the exception of Moloney leukemias. Cytotoxicity of the tumors was expressed as percent of stained, dead cells. At anti-G serum dilutions of 1/16, BALB mice showed high percentages of dead cells when inoculated with cells from normal BALB tissue (97%), spontaneous BALB leukemia (60%), and sarcoma 180 (71%). Lowest percentages of dead cells were found in mice given cells from leukemias induced by X-ray (8%), human leukemia (11%) and spontaneous AKR leukemia (10%). Leukemias and tumors of A and Rockland strain mice were G-negative. Syngeneic transplants of sarcoma 180 were G-positive in BALB mice and G-negative in Rockland mice. Normal AKR tissue increased in degree of G-positivity as the animals receiving implants increased in age. Apparently either the Gross virus or a relative of it is present in BALB mice in a latent state, becoming detectable upon the induction of leukemia or tumors by various inducing agents. The Gross virus, therefore, appears to have a role in malignant transformation consequent to the administration of an inducing agent.

- 1524 NEUTRALIZING ANTIBODIES TO SIMIAN VIRUS 40 (SV40) IN HUMAN SERA. (E.) Hahn, E. E. A. (Serafino Belfanti Milanese Sieroter. Inst., Italy). *Progr Immunobiol Stand* 3:44-47, 1969.

Laboratory workers having daily contact with monkeys were examined for neutralizing antibodies to SV40. Five persons who had contact with monkeys daily for periods of 4-6 hr donated serum samples which were found to be positive for SV40 antibodies, with titers ranging from 1:4-1:16. One veterinary worker with exposure to monkeys was antibody-negative. None of 20 sera taken from healthy blood donors without exposure to monkeys showed SV40 antibodies. Nineteen of these controls had been vaccinated with inactivated SALK polio vaccine. Apparently, SV40 had been transmitted from the monkeys to the animal handlers in the laboratory.

- 1525 PROPERTIES OF TRANSFORMED HAMSTER CELLS CONTAINING SV40 TUMOR ANTIGEN IN THE CYTOPLASM. (E.) Richardson, L. S. (Baylor Coll. Med., Houston, Tex.) and J. S. Butel. *Int J Cancer* 7(1):75-85, 1971.

The immune properties of transformed hamster cells containing SV40 tumor antigen in the cytoplasm were investigated. Eight transformed cell lines were established from tumors induced in 8 of 20 hamsters by hamster embryo fibroblasts which had been transformed *in vitro* by PARA-adenovirus 7. All of the tumor cell lines contained SV40 tumor antigens; in 6 of the 8 cell lines, antigen was contained in the cytoplasm exclusively, while in 2 lines antigen was found in nucleus and cytoplasm. All cell lines contained SV40 surface antigen; none contained adenovirus tumor antigen. Seven of 8 hamster sera contained SV40 tumor antibody; 3 serum samples produced adenovirus tumor antibody and 1 produced SV40 surface antibody. Tumor antigen remained localized in the cytoplasm in 5 of the 6 cell lines through 30 passages *in vitro*; antigen in the 6th cell line became localized in the nucleus after passage 23. Complement fixation tests and immunofluorescence tests successfully demonstrated cytoplasmic tumor antigen. When transformed cells containing cytoplasmic SV40 tumor antigen were transplanted *in vivo* to weanling hamsters, tumors developed in the majority of recipient animals with latencies of 2-9 wk. The transplanted cells contained SV40 tumor specific transplantation antigen.

- 1526 AMINO ACID PATTERN OF RIBONUCLEOPROTEIN AND PURIFIED T-ANTIGEN ISOLATED FROM HAMSTER TUMORS INDUCED BY ADENOVIRUS TYPE 12. (Rus.) Degtyarenko, V. I. (I. I. Mechnikov Sci. Res. Inst. Virol., Epidem., Odessa, U.S.S.R.), N. I. Zatsepin and A. V. Pertaya. *Biokhimiia* 35(6):1110-1112, 1970.

The amino acid composition of purified T-antigen and of the acid ribonucleoprotein isolated from adenovirus type 12-induced hamster tumors were found to have certain analogies. The contents of leucine, phenylalanine, valine, tyrosine, glutamic acid, threonine and serine were similar in both preparations. Differences were noticed in the contents of aspartic acid, glycine, histidine and aminobutyric acid. Tryptophan was not detected in the T-antigen protein but was present in the acid ribonucleoprotein. The T-antigen was composed of 22.7% of monoaminodicarboxylic acids, indicating it to be an acid protein. The highly lipophilic properties of the T-antigen were

considered to be due to its high content of aliphatic amino acids.

- 1527 THE "IMMUNOLOGIC DETERMINANTS" IN THE AVIAN ONCOGENIC VIRUS SYSTEM. PURIFICATION AND IMMUNOCHEMICAL CHARACTERIZATION OF THE ANTIGEN COMPLEX IN THE GROUP OF CHICK CELLS TRANSFORMED BY ROUS SARCOMA VIRUS (SCHMIDT-RUPPIN STRAIN). (Fr.) Rabotti, G. F. (Lab. Exp. Med. Coll. France, Paris) and B. Teutsch. *C R Acad Sci* 272(2):343-346, 1971.

The specific antigen of the avian sarcomas was shown to possess 4 distinct antigenic components: α_0 , α_1 , β and γ . By means of immunodiffusion and electrophoresis it was possible to separate out 3 distinct peaks: a double-peak in the area of gamma-globulin, another corresponding to beta-globulin and a third peak towards the anode. Three main active antigens appeared to be present in the antigen specific for the chick group, which were separable according to their molecular weight, the one with the highest molecular weight being double. After many trials, it was found that the most favorable chromatographic separation was with DEAE-Sephadex at pH 8.6 and that the α_0 and α_1 antigens could be eluted by the initial buffer, whereas β and γ were recovered in the fractions containing 0.02 to 0.1 M NaCl. A nomenclature is proposed on the basis of the antigenic activity.

- 1528 INTERFERON SYSTEM IN CELLS FROM HUMAN TUMORS AND FROM PERSONS PREDISPOSED TO CANCER. (E.) Worthington, M. (Natl. Inst. Allerg. Infect. Dis., Natl. Inst. Hlth., Bethesda, Md.) and S. A. Aaronson. *Infect Immun* 3(3):424-428, 1971.

The response of the interferon system in fibroblasts from persons predisposed to leukemia, fibroblasts from persons with neoplastic disease and in human tumor cells to polyinosinic-polycytidylic acid (poly I:C) and Chikungunya virus stimulation was evaluated. The minimal effective concentrations of poly I:C needed to induce resistance to Sindbis virus was 1 μ g/ml or less for all but one of the skin fibroblasts tested, while normal fibroblast cultures as well as lung, kidney, muscle and synovium showed complete suppression of Sindbis virus hemagglutination when treated with 10^{-4} dilution of Chikungunya virus. Cell lines derived from 4 sarcomas and 1 bronchogenic carcinoma were relatively resistant to the above poly I:C concentrations and Chikungunya virus dilution. However, at concentrations 10-100-fold greater, the Chikungunya virus was protective. The minimum effective concentration of human interferon for non-tumor cells was 5 U/ml or less, whereas 4 of the 5 tumors required concentrations of 50 U/ml, with the tumor most responsive to human interferon showing greatest sensitivity to the protective effects of both poly I:C and Chikungunya virus. The majority of tumor cells stimulated with heat-inactivated Chikungunya produced 30 U/ml or less of interferon in response to a 10^{-2} dilution of the virus, whereas nontumor cells produced at least 100 U/ml. Three of the tumor cell lines and 1 skin fibroblast strain

were found to contain mycoplasma contamination; however, these did not cause cells to become resistant to the antiviral effects of either poly I:C or interferon.

- 1529 IMMUNOSUPPRESSION BY LEUKEMIA VIRUSES: ULTRASTRUCTURAL STUDIES OF ANTIBODY-FORMING SPLEENS OF MICE INFECTED WITH FRIEND LEUKEMIA VIRUS. (E.) Koo, G. C. (Temple U. Sch. Med., Philadelphia, Pa.), W. S. Ceglowski and H. Friedman. *Immun* 106(3):799-814, 1971.

Male mice inoculated with infectious doses of Friend leukemia virus before being immunized with 0.5 ml a 10% sheep RBC suspension showed an impaired immune response to the sheep cells compared to mice infected with virus after immunization. Spleens of mice infected with virus 3 and 8 days before immunization had 95% and 98% fewer antibody plaque-forming cells than spleens of mice given sheep erythrocytes without virus infection. While mean serum antibody titers for uninfected, immunized mice and for mice immunized and infected on the same day were 7.0, 10.0 and 5.0, respectively, for mice infected 3 and 8 days before immunization were 5.0 and 4.0, respectively. The ultrastructure of spleens of uninfected, immunized mice was marked by abundant lymphoid cells and macrophages as well as plasmablasts. Spleens of mice infected with Friend virus 2 days before immunization were similar to spleens of uninfected mice; however, very few plasmablasts were seen in spleens of mice infected 3 days before immunization. Immature lymphoid cells and blast cells being the predominant cell types in these spleens. Immature neoplastic cells containing viral particles were so common in spleens infected before immunization. Infiltration of leukemic cells was even more pronounced in spleens of mice infected with virus 8 days before immunization with sheep red blood cells and virus particles were abundant. Plasma cells were not found in these spleens, and virus particles were seen budding from lymphocyte membranes. The results appear to be a competition between leukemia virus and antigen for common stem cells.

- 1530 IMMUNOLOGIC DEFICIENCY ASSOCIATED WITH MAMMARY TUMOR VIRUS (MTV) INFECTION IN MICE: HEMAGGLUTININ RESPONSE AND ALLOGRAFT SURVIVAL. (E) Blair, P. B. (Sept. Pact., Immun., U. California, Berkeley), M. L. Kripke, M. A. Lappe, R. Bonhag and L. Young. *J Immun* 106(2):364-370, 1971.

Female mice infected with mammary tumor virus (MTV) prior to immunization with sheep red blood cells showed lower mean hemagglutinin antibody titers than did immunized mice not infected with MTV. Immunized mice which were not infected produced high hemagglutinin titers (peaks at 9000-13000) 30 days after immunization with sheep erythrocytes. Six-month-old mice produced higher hemagglutinin titers than 8, 10 or 12-month-old mice. BALB/c mice developed higher mean titers than did BALB/cfC3H mice. Mice injected with MTV 4 days prior to immunization developed lower hemagglutinin titers than did uninfected mice; in both groups maximum titers were attained 5-7 days after immunization.

zation. Uninfected mice had mean hemagglutinin titers of 8.14 (\log_2 titer), while infected mice had mean titers of 5.29. Differences between infected- and uninfected-hemagglutinin titers were statistically significant only for serum samples collected from 7-month-old mice. Skin allografts survived longer on virus-infected mice than on uninfected mice. Immunologic deficiency was generally more pronounced in infected mice 10 months of age and older than in younger animals.

- 1531 IMMUNE RESPONSE TO GROSS VIRUS-INDUCED LYMPHOMA: II. KINETICS OF THE CELLULAR IMMUNE RESPONSE. (E.) Oren, M. E. (Yale-New Haven Hosp., Conn.), R. B. Herberman and T. G. Canty. *J Nat Cancer Inst* 46(3):621-628, 1971.

Subcutaneous inoculation of rats with 5×10^7 cells from a Gross virus-induced ascites lymphoma induced tumor nodules in 4 days which regressed by day 17; the cellular and humoral immune response of spleen cells to these tumor cells was investigated. Cellular cytotoxicity in mouse spleen cells, first noticeable on day 6 postinoculation, reached maximum values of 18% on day 10, and declined to near zero through day 50. Humoral antibody titers showed 2 peaks, the first occurring on day 10 (mean antibody titer of 55) and the second occurring on day 35 (mean titer of ~250); humoral antibody titers dropped to less than 10 between peaks. The height of the cellular immune response depended on the size of the initial dose of tumor cells and on the length of incubation time; cellular cytotoxicity for spleen cells of rats given doses with a spleen cell:tumor cell ratio of 50 was half that of spleen cells of rats given doses with a spleen cell:tumor cell ratio of 200. Spleen cells incubated for $1\frac{1}{2}$ hr had maximal cellular cytotoxic values which were less than a third those of spleen cells incubated for 4 hr. Increased cellular cytotoxicity could not be produced by inoculation of a second dose of tumor cells at 30-40 days after the initial inoculum.

- 1532 FLUORESCENCE COMPLEMENT FIXATION BY LYMPHOBLASTOID CELLS. (E.) Floyd, R. (Baylor Coll. Med., Houston, Tex.), V. Vonka and M. Benyesh-Melnick. *J Nat Cancer Inst* 46(2):383-390, 1971.

The presence and location of intracellular Epstein-Barr virus-soluble complement-fixing antigens were studied in 11 lymphoblastoid cell lines derived from normal individuals and from individuals with Burkitt lymphoma, infectious mononucleosis, acute myelogenous leukemia and acute lymphoblastic leukemia by means of fluorescence complement-fixation. Cells from the Burkitt lymphoma line possessed cytoplasmic fluorescence in 3-7% of cells, and nuclei were left unstained, while 10-12% of cells of the lymphoblastoid line obtained from an individual with infectious mononucleosis fixed complement in the absence of antiserum. All cells that fixed complement from the Burkitt lymphoma line possessed the Epstein-Barr virus, and 30-40% of the cells associated with mononucleosis were positive for the presence of the virus. All other cells tested gave negative results. One reason for the results noted could be the accumulation of

globulins produced by the cells or the presence of an antibody in the guinea pig serum used in the complement fixation test which was able to fix complement after forming an antigen-antibody complex with the antigen in the cell. However, this latter hypothesis is unlikely since guinea pig serum did not reveal any anti-Epstein Barr virus antibodies when followed with fluorescein-conjugated antiguinea-pig gamma globulin.

- 1533 CELL SURFACE ANTIGENS DETECTABLE BY CYTOTOXIC TEST ON FRIEND VIRUS-INDUCED AND FRIEND VIRUS-INFECTED TUMORS IN THE RAT. (E.) Shirai, T. (Hosp. Special Surg., New York, N. Y.), H. Kaji, N. Takeichi, F. Sendo, H. Saito, M. Hosokawa and H. Kobayashi. *J Nat Cancer Inst* 46(3):449-460, 1971.

The biological role of the antigen specified by Friend virus in relation to growth of tumors and its effect on other antigenic components of the cell surfaces of nonviral tumors were analyzed in rats of the Wistar-King-Aptekman, Wistar/Mk and Donryu strains by means of cytotoxic and quantitative absorption testing. Friend virus-induced rat tumors were distinguished by their growth rates following s.c. transplantations in which 2 failed to grow almost completely, and transplants of another grew to 20 mm average tumor diameter but ultimately regressed. A subline of this tumor resulted in lethal growth in normal adult Wistar-King-Aptekman rats. Cytotoxic effects of the Friend-specific antiserum were inversely related to growth rates *in vivo* for all tumor cell lines; Friend-virus infected cell lines were markedly sensitive to the antiserum. Rats that had resisted transplants of Friend virus-infected tumors acquired high transplantation resistance against syngeneic non-virus-infected tumors, and no cytotoxicity was demonstrated with other tumor cells to antiserum obtained from those rats.

- 1534 DEFECT IN CELLULAR IMMUNITY OF LEUKEMIA VIRUS-INFECTED MICE ASSESSED BY A MACROPHAGE MIGRATION-INHIBITION ASSAY. (E.) Friedman, H. (Temple U. Sch. Med., Philadelphia, Pa.) and W. S. Ceglowski. *Proc Soc Exp Biol Med* 136(1):154-158, 1971.

Cellular immunity of mice infected with Friend leukemia virus (FLV) was studied using an *in vitro* macrophage migration-inhibition assay to assess immunocompetence of mice to antigens of tubercle bacilli (PPD). Normal migration of peritoneal cells from nonleukemic mice immunized with Freund's complete adjuvant was readily inhibited *in vitro*. Addition of PPD to cell suspensions resulted in a significant decrease in the area of migration in the range of 40-60% with the inhibition reaction appearing maximally when the mice had been sensitized for 2-3 wk before sacrifice. The migration activity of peritoneal cells from both immunized and non-immunized FLV-infected mice was not inhibited by PPD. Rapid development of splenomegaly and blood cell dyscrasia culminating in erythroblastic leukemia was seen in FLV-infected mice. Failure to detect cellular immunity in FLV-infected mice correlates with the

marked decrease in humoral immunity previously assessed by skin graft rejection assays.

- 1535 IMMUNOSUPPRESSION BY LEUKEMIA VIRUSES:
VI. ULTRASTRUCTURE OF INDIVIDUAL ANTIBODY-
FORMING CELLS IN THE SPLEENS OF FRIEND LEUKEMIA
VIRUS-INFECTED MICE. (E.) Koo, G. C. (Temple U. Sch.
Med., Philadelphia, Pa.), W. S. Ceglowski, M. Higgins
and H. Friedman. *J Immunol* 106(3):815-830, 1971.

Typical murine leukemia virus particles were found in the plaque-forming cells (PFC) in spleens of mice infected with Friend leukemia virus 8 days before immunization with sheep RBC. Spleens of virus-infected and immunized mice contained 98% fewer PFC than spleens of mice immunized with sheep RBC but not inoculated with Friend virus. Plasma cells at various stages of maturity comprised all of the antibody-forming cells in the spleens of the latter group of mice; these plasma cells were either proplasmacytes (24%) or mature plasma cells (56%). About 20% of the PFC cells in the spleens of uninfected mice appeared to be degenerated with no structural organization to the nuclei. Sixty-four percent of the PFC from uninfected spleens contained virus-like intracisternal A-type particles; particles were found only in the intracisternal spaces of the endoplasmic reticulum of the plasma cells. The PFC of spleens of mice infected with Friend virus prior to immunization were comprised of proplasmacytes (10%) or mature plasma cells (60%); degenerated cells accounted for 20% of the PFC in these cells. Friend leukemia virus C type particles were found in 55% of these spleen cells, usually at the cytoplasmic membrane. These particles were larger than the particles seen in spleens from uninfected mice and were never found in the endoplasmic reticulum. Apparently, leukemia virus infection and antibody formation are not mutually exclusive processes at the level of the single spleen cell.

- 1536 DEMONSTRATION BY THE ANTIGLOBULIN CONSUMPTION TEST WITH MURINE ANTISERA OF COMMON ANTIGENS IN TISSUES INFECTED WITH THE MAMMARY TUMOR VIRUS FROM DIFFERENT MOUSE STRAINS. (E.) Holmes, E. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and D. L. Morton. *J Nat Cancer Inst* 46(2):253-260, 1971.

Mammary tumor virus antigens were prepared from tumors in mice known to contain this virus, and anti-mammary tumor virus antisera were prepared by injection of histoincompatible mammary tumors induced by the virus into mammary tumor virus-free mice. In an antiglobulin consumption test, antisera were reacted against tissues infected with the mammary tumor virus, and absorption of the anti-mammary tumor virus antibody by some virus-infected tissues was observed. It was found that mammary tumor virus prepared from tumors carried by mouse strains C3H/HeN, DD/He, DBA/2JN, A/He, RIII/An, and BALB/cf appeared to share a common antigen related to the mammary tumor virus.

- 1537 DIFFERENCES IN THE MANIFESTATION OF VIRUS SPECIFIC SURFACE ANTIGEN BETWEEN CELLS TRANSFORMED BY SV40 AND UV-IRRADIATED SV40. (E.) Klietmann, W. (Inst. Hyg., U. Freiburg, Germany) and N. Seemayer. *Int J Cancer* 7(1):50-58, 1971.

SV40 virus exposed to UV or inactivated by white light after photosensitization by toluidine-blue was not as antigenic as non-inactivated or control virus. Normal and transformed hamster cell lines were inoculated with inactivated or control SV40, and antigenic response to antisera prepared in hamsters by injecting them with varying amounts of SV40 was studied by the mixed hemagglutination reaction (MHA). SV40-specific surface antigen was demonstrated by MHA on hamster tumor cells induced by non-irradiated SV40. Hamster cells transformed by control SV40 were positive for both surface and tumor antigen of SV40; UV-irradiation of virus for 12 min produced a line of transformed cells of reduced infectivity by 5 log₁₀ steps and diminished the surface antigen response. Other cells transformed by UV-irradiated SV40 were negative or showed a strongly diminished tumor antigen response and a diminished surface antigen response. The infectivity of cells transformed by photosensitized and white-light exposed SV40 were positive for tumor antigen and showed diminished SV40 surface antigen response. Cell lines induced by control SV40 yielded positive antigenic reactions up to anti-serum dilutions of 1:12; however, cells transformed by SV40 inactivated by UV or by white light only gave positive results in MHA at antiserum dilutions of 1:80 and 1:160, respectively. After 3 inoculations into adult hamsters, control SV40 induced a specific transplantation resistance to SV40-transformed tumor cells which fully protected the recipient hamsters from tumor development. Hamsters immunized with UV-irradiated SV40 developed tumors in more than 50% of the cases. All cell lines with diminished surface antigen caused malignant tumors when inoculated into adult hamsters.

- 1538 THE USE OF AN *IN VITRO* TEST FOR THE ESTIMATION OF PRESENCE OF THE SPECIFIC TUMOR ANTIGEN OF THE TRANSPLANTATION TYPE INDUCED BY SV40 VIRUS. (E.) Pekarek, J. (Res. Inst. Immun., Prague, Czechoslovakia), J. Svejcar, V. Vonka and H. Zavadil. *Progr Immunobiol Stand* 3:365-368, 1969.

Changes in the migration activity of cells of mesenchymal origin as a reaction specific for delayed hypersensitivity following infection with simian virus 40 were studied by means of spleen fragment cultivation. Migration activity of spleen cells from hamsters made resistant to the transplantation of tumor cells was considerably inhibited during cultivation in the presence of transformed cells; in the presence of normal cells their migration activity was comparable to that of control hamsters. Secondary green monkey kidney cell cultures infected with simian virus 40 and spleen fragments from either infected or non-infected cells of control hamsters was not substantially influenced, but inhibition of migration was observed with spleen cells of resistant hamsters.

hamsters in the presence of infected cell monolayers; its rate was dependent on the period after infection, and the most marked results were seen in cultures infected 24 hr prior to addition of the fragments. These results seem to demonstrate the presence of the surface antigen of simian virus 40 transformed cells in cell cultures undergoing a cytolytic infection.

1539 MALIGNANT LYMPHOMAS AND PLASMACYTOSIS IN MICE UNDER PROLONGED IMMUNOSUPPRESSION AND PERSISTENT ANTIGENIC STIMULATION. (E) Krueger, G. R. F. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), R. A. Malmgren and C. W. Berard. *Transplantation* 11(2):138-144, 1971.

Mice of 2 strains (BALB/c and C57B1) were given immunosuppressive treatment by azathioprine (15 mg/kg/day), or antilymphocyte serum (ALS, 0.25 ml) and antigenic stimulation by i.p. injections of lactic dehydrogenase virus (LDV), Freund's adjuvant (0.05 ml doses), viable HeLa cells, or vaccination with smallpox vaccine. Control mice went untreated or were given either antigenic stimulation or immunosuppressive treatment alone. Hyperplasia in lymphoreticular tissue was seen in all mice, control as well as experimental, except mice given LDV and ALS and untreated controls. Mice given antigenic stimulation alone, of whatever type, showed secondary follicles, plasma cell differentiation in the medullary cords, and activation and pyroninophilia of reticulum cells in the perifollicular area. Mice on azathioprine treatment alone showed depletion of the small lymphocytes from lymph nodes and spleen. Mice on ALS treatment alone showed small lymphocyte depletion and an increase of plasma cells in the medullary cords of lymph nodes. Malignant lymphoblastic lymphomas developed in 20% of BALB/c mice given azathioprine and antigens. No control mice developed lymphomas. Forty percent of BALB/c mice and 27% of C57B1 mice given ALS, with or without antigens, developed immature plasmacytoses; chronic treatment with ALS led to membrane glomerulitis and glomerulonephrosis in 8% of ALS-treated mice. Mice given antigens in addition to chronic ALS treatment showed the most severe glomerulonephrosis. Circulating antigen-antibody complexes were thought to cause the kidney lesions, and the lymphomas were seen as a result of antigenic stimulation under immunosuppressed conditions.

1540 IMMUNOSUPPRESSION BY ANTILYMPHOCYTE SERUM AND ITS EFFECT ON TUMORS INDUCED BY 3-METHYLCHOLANTHRENE IN MICE. (E.) Wagner, J. L. (Sch. Med. U. North Carolina, Chapel Hill) and G. Haughton. *J Nat Cancer Inst* 46(1):1-10, 1971.

The effect of prolonged diminution of, or abrogation of, the graft rejection response by heterologous antilymphocyte serum (ALS) on the incidence and latency of tumors induced by a standard dose of chemical carcinogen (0.25-0.50 mg of 3-methylcholanthrene, MCA) was tested in mice of both sexes. Seventy-three percent of the mice injected with (ALS) 50 days after injection of MCA and surviving after 400 days developed tumors compared to 78% of the

control group which received no ALS. However, only 9% of those injected with ALS survived in comparison to 15% of the control group, and metastases occurred in 27% and 19%, resp. Of 68 mice treated with ALS on the day of MCA administration, only 1 animal failed to develop tumors compared to 5 of 88 of the control group. Over a 12-week period more ALS-treated mice died with tumors than did mice injected with carcinogen only or control groups receiving nothing. After 152 days, 46 of 50 mice treated with ALS and 45 of 50 mice treated with carcinogen had palpable tumor with no difference either in latency or in total incidence of MCA-induced tumors. The death rate in mice receiving a standard dose of MCA and treated with immunosuppressant did not differ from the group receiving carcinogen alone. The immune response which can be suppressed with ALS is largely ineffectual in preventing the appearance of primary neoplasms induced by injection in mice of 250 to 500 µg of MCA; however, the graft rejection response was suppressed by ALS for at least 84 days.

1541 THE EFFECT OF ANTILYMPHOCYTE SERUM ON EXPERIMENTAL HAMSTER BUCCAL POUCH CARCINOGENESIS. (E.) Giunta, J. L. (Tufts U. Sch. Dent. Med., Boston, Mass.) and G. Shklar. *Oral Surg* 31(3):344-353, 1971.

The effect of systemically injected anti-hamster lymphocyte serum (ALS) on 7,12-dimethylbenz(a)anthracene (DMBA)-induced epidermoid carcinogenesis of the buccal pouch has been studied in male and female Syrian hamsters through cytologic analysis. Painting with DMBA resulted in a generalized whitened, granular surface interspersed with erythematous areas, and tumor masses which were well-defined raised papillary and nodular lesions with some ulceration and hemorrhage. ALS/DMBA pouches appeared to present lesions at earlier stages than those of the DMBA group with more extensively altered areas showing patterns of dyskeratosis and frank carcinoma alternately. Many anaplastic lesions appeared in the ALS/DMBA group compared to solitary ones among the DMBA group. Spleens in the ALS/DMBA group had a disorganized architecture with scanty lymphatic nodules as well as sinusoids engorged with lymphocytes and erythrocytes, whereas the DMBA control group had essentially normal spleens. Lymph nodes in the DMBA group were slightly to moderately enlarged with prominent germinal follicles and dilated central sinusoids, whereas the ALS/DMBA group gave evidence of normal or slightly enlarged nodes with consistently sparse germinal follicles. However, at later periods nodes in the latter group became moderately to severely enlarged with disorganized architecture obliterated by a proliferation of "blast" type cells throughout. No metastases were found in either experimental group at the termination of the experiment at 16 wk.

1542 HL-A ANTIGENIC LOSS IN MALIGNANT TRANSFORMATION. (E.) Seigler, H. F. (Duke U. Med. Ctr., Durham, N. C.), W. B. Kremer, R. S. Metzgar, F. E. Ward, A. T. Haug and D. B. Amos. *J Nat Cancer Inst* 46(3):577-584, 1971.

In vitro isoantigenic changes of antigens were studied in the peripheral lymphocytes of a patient with malignant lymphoma. Cytotoxicity reactions with HL-A antiserum were negative for HL-A antigens on the lymphocyte specified by the patient's genotype as the malignant lymphoma with normal peripheral lymphocytes progressed to disease with circulating neoplastic lymphocytes. Absorption of 3 positively reacting antisera with abnormal lymphocytes from the patient failed to remove their cytotoxicity, whereas cells from the HL-A identical sibling lost all cytotoxic activity. Skin fibroblasts demonstrated the same serologic reaction pattern as the initial typing on the peripheral lymphocytes, indicating that the patient's membrane-associated isoantigens remained unaltered, while the malignant lymphoid cells demonstrated a loss of reactivity with HL-A antisera. In response to phytohemagglutinin, lymphocytes obtained at the time of remission showed a low uptake of precursors while the abnormal cells obtained when the disease was again active gave evidence of increased incorporation of precursors into RNA, DNA, and protein synthesis with a decline in synthetic capability after 72 hr.

- 1543 EFFECTS OF ANTILYMPHOCYTE SERUM (ALS) ON THE INDUCTION OF LYMPHOCYTIC LEUKEMIA IN MICE. (E.) Law, L. W. (Natl. Cancer Inst., Natl. Inst. Hlth, Bethesda, Md.) and S. S. Chang. *Proc Soc Exp Biol Med* 136(2):420-425, 1971.

The relationship between immunologic reactivity, using antilymphocyte serum as an immunosuppressant, and the induction and repression of lymphocytic neoplasms in adult BALB/c mice infected with murine leukemogenic virus was studied by determining virus and virus neutralizing antibody titers. Twelve-week old animals resisted the leukemogenic effect of the i.p. injection of murine leukemia virus compared to those receiving antilymphocyte serum in which lymphocytic leukemia was detected as early as 1.5 months after infection with death following within 2 wk. Antilymphocyte serum alone was ineffective, and normal rabbit serum was previously observed not to influence murine leukemia virus induction of lymphocytic leukemia. However, an unexpected finding was the lack of response to the leukemogenic effects of the virus in antilymphocyte serum-treated animals 6-8.5 months of age at the beginning of treatment in 15 mice. Reversal of susceptibility in serum-treated animals by adoptive transfer of syngeneic adult normal lymphoid cells was accomplished and probably represents replacement of those immune elements removed by the antilymphocyte serum.

- 1544 REAPPEARANCE AND RELATIVE IMPORTANCE OF IMMUNOCOMPETENT CELLS IN THE THYMUS, SPLEEN AND LYMPH NODES FOLLOWING LETHAL X-IRRADIATION AND BONE MARROW RECONSTITUTION IN MICE. (E.) Blomgren, H. (Karolinska Inst., Stockholm, Sweden) and B. Andersson. *J Immunol* 106(3):831-834, 1971.

The reappearance of immunologic competence in 1-month-old (A.CA x C57BL) F_1 hybrid mice following lethal X-irradiation and bone marrow reconstitution were followed at the whole animal level and in various lymphoid

cell populations. Groups of mice injected with sheep erythrocytes showed peak antibody titers from 2.7 to 4.0 log₁₀ on day 6 in unirradiated animals used as controls, and slightly enhanced response was noted in irradiated mice given 10⁷ thymus cells. In irradiated mice, mice challenged on day 0, with sheep erythrocytes showed no response, and peak titers were obtained on day 20; enhancement of response was seen in animals receiving thymic cells along with the erythrocytes. As the time of immunization after irradiation was increased from 0 to 25 days in irradiated mice injected with or without thymic cells, recovery progressively increased to give peak titers ranging from 0.00 for the spleen on day 14 to 3.10 for thymus cells on day 25. Thymus-dependent lymphocytes, although not known to produce humoral antibodies themselves, seem to enhance antibody formation against certain antigens. Origin of these cells is not known.

- 1545 *IN VITRO* ASSAY OF CELL MEDIATED IMMUNITY IN HUMAN CANCER: DEFINITION OF LEUKOCYTE MIGRATION INHIBITORY FACTOR. (E.) Wolberg, W. H. (U. Wisconsin Med. Sch., Madison) and M. L. Goelzer. *Nature* 229(5287):632-634, 1971.

The migration of leukocytes incubated with human tumor cells was investigated in order to elucidate the diminution of the cutaneous hypersensitivity response to tumor cells obtained from breast carcinomas, bronchogenic carcinomas, and other tumors. When tumor cells were incubated with the patient's leukocytes, it appeared that the tumor cells liberated a substance which inhibited migration of the leukocytes by as much as 79% in some preparations. The addition of phytohemagglutinin to the preparation also inhibited leukocyte migration. Partial reversal of this inhibition occurred when blastogenesis was blocked by 5-fluorodeoxyuridine in concentrations greater than 1 x 10⁻⁷M. Human tumors apparently contain or produce a substance which inhibits *in vitro* migration of leukocytes obtained from the individual in whom the tumor arose. This substance may adversely affect the defensive delayed hypersensitivity reaction in the host.

- 1546 CELL CULTURE OF THREE ANTIBODY-PRODUCING MURINE PLASMACYTOMAS. (E.) Periman, P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Nat Cancer Inst* 46(2):403-410, 1971.

Plasmacytomas originally induced by mineral oil injections in mice were maintained as 3 cell lines *in vitro* for as long as 24 months in one case. All 3 cell lines were composed largely of mononuclear round cells having prominent Golgi apparatus, and many free ribosomal particles and extensive rough endoplasmic reticulum. Numerous intracisternal A-type particles with 2 electron-dense membranes and a lucent center were found in the rough endoplasmic reticulum. When viable cells from the 3 lines were injected s.c. in mice, plasma cell tumors resulted which secreted immunoglobulins with the same antibody activity as those produced by the original tumor; light chain was found by immunodiffusion in the urine of mice bearing tumors produced by cell culture inocula. The cell lines maintained

in vitro also produced immunoglobulins antigenically similar to those produced by the parent tumors, and also secreted the same types of light and heavy chains which were secreted by parent tumors.

- 1547 COMPARISON OF ACTIVE AND ADOPTIVE IMMUNITY INDUCED BY A CONGENITAL MOUSE TUMOR. (Fr.) Oth, D. (Fac. Sci. Nancy, France), M. Bujadoux and C. Burg. *C R Soc Biol* 164(5):1104-1108, 1970.

Experiments are described in which immunization of mice with congenital tumors (C57Br) was carried out by the transfer of about 10^8 immunocompetent cells taken from animals previously immunized against this tumor. The number of cells injected was far less than the total immunocompetent cells present in the donor animal, and it was assumed that the adoptive immunity would be less than that of the active immunity normally obtained. The results, however, revealed that the actively immunized animals were less immune to tumor transplantation than the ones immunized adoptively when calculated in terms of survival. This result may be explainable on the basis that at the time of the inoculation of the viable tumor, the number of immunocompetent cells immunized against the tumoral neoantigens was greater in the adoptive immunity group than in the active immunity group. In the present study, the immunocompetent cells sensitized against specific tumoral antigens may have multiplied more quickly than the others when transferred to nonimmunized animals. Regulator feed-back mechanisms in the synthesis of antibodies are discussed.

- 1548 THE CELL SITE OF THE IMMUNOLOGICAL DEFECT IN TUMOR-BEARING MICE. (E.) Bianco, G. (Harvard Med. Sch., Boston, Mass.), B. L. Brown, E. E. Jones and V. M. Rosenoer. *Proc Soc Exp Biol Med* 136(2):507-509, 1971.

Observation of the primary immune response in mice bearing implants of the Ridgeway osteogenic sarcoma indicated that when the tumor was far advanced, the capacity of host spleen cells to respond to injections of sheep erythrocytes was impaired; when the tumor weighed 3 g the number of plaques/spleen was 36% of control values, and 1 day later the number of plaques was 5% of control. Normal mice given injections of sheep RBC showed slight splenic enlargement and some increase in mitotic figures; mice bearing sarcomas had striking splenomegaly and prominent mitotic figures. Sarcoma bearing mice injected with sheep erythrocytes showed similar splenic changes, but the degree of the changes was more advanced. Apparently, the major process resulting in splenomegaly in tumor-bearing mice was hyperplasia, acting predominantly in the lymphoid cells. In *in vitro* experiments, spleen cells of mice were treated to separate macrophage cells and lymphocytes, and the macrophage cells from tumor-bearing mice were combined with normal lymphocytes or with lymphocytes from the tumor-bearing mice which were the source of the macrophage cells. Lymphocytes from tumor-bearing mice produced fewer plaques when incubated with macrophage from control mice than lymphocytes

from control animals incubated under similar conditions. Macrophage cells from tumor-bearing animals behaved normally when combined with control lymphocytes, suggesting that the immune defect in tumor-bearing mice was located in the lymphocyte cell population of spleen cells.

- 1549 ISOLATION OF METH A CELL SURFACE MEMBRANES POSSESSING TUMOR-SPECIFIC TRANSPLANTATION ANTIGEN ACTIVITY. (E.) McCollister, D. L. (Francis Delafield Hosp., New York, N. Y.). *Cancer Res* 30(12):2832-2840, 1970.

A method is described for the isolation of surface membranes from transplanted Meth A ascites tumor cells in BALB/c mice and leukemic cells of AKR/J mice and the detection of tumor-specific transplantation antigen activity through centrifugation and phase and electron microscopy. The isolation of surface membrane ghosts appeared to depend upon the borate present in the harvesting solution; the process was followed microscopically, showing final pellets of both types of cells to be white, and under phase microscopy showed slight swelling of the cell, Brownian movement of intracellular particles and, finally, a bursting of the cell with or without expulsion of the nucleus. Completely detached membrane ghosts were recovered and appeared as structureless bags offering very little contrast, especially where free of all visible structures, with greatest contrast appearing at the periphery or where the membrane was folded or torn. Under electron microscopy linear elements with trilamellar structures typical of biological membranes about 80 Å thick and devoid of mitochondria and nuclei were observed. Estimates made from counts on recovered ghosts and the number of whole cells just prior to extraction indicated that ghosts were recovered from 10-50% of the Meth A cells and 50-70% of the AKR/J leukemic cells (1 ml of packed Meth A cells yielded about 0.73 mg of lyophilized material in isolated ghost fraction). Ghosts of both types of cells may be transformed to a microscopically invisible state by 20 forceful passages with a syringe through a No. 21 needle. Female mice immunized with either Meth A or AKR/J leukemic cell membrane suspensions or disrupted Meth A ghosts and subsequently challenged with freshly harvested, viable Meth A cells showed a mean survival time of 17.1 to 21.2 with the higher rate among those immunized with disrupted Meth A ghosts. The number of animals surviving a 60 or 80-day period ranged from 0/10 to 10/12 with the highest incidence of survival appearing among animals treated with higher concentrations of either whole or disrupted Meth A ghosts. Whether or not true tumor-specific transplantation antigen activity is associated with surface membrane ghosts needs clarification with experimentation with autochthonous tumors.

- 1550 DEMONSTRATION BY COLONY INHIBITION METHODS OF CELLULAR AND HUMORAL IMMUNE REACTIONS TO TUMOR-SPECIFIC ANTIGENS ASSOCIATED WITH AMINOAZO-DYE-INDUCED RAT HEPATOMAS. (E.) Baldwin, R. W. (Cancer Campaign Res. Lab., U. Nottingham, England) and M. J. Embleton. *Int J Cancer* 7(1):17-25, 1971.

Hepatomas were induced in rats by p.o. administration of 4-dimethylaminoazobenzene; tumor cells were inactivated by exposure to 15,000 r of X-irradiation, and then were used to immunize rats against hepatoma transplants. Implantation of irradiated hepatoma cells caused immunized rats to reject tumor cell challenges in 100% of cases. Lymph node cells from immunized rats were incubated with hepatoma cells, with the result that in 15 of 17 colony-inhibition tests, lymph nodes from immune rats inhibited colony formation by tumor cells; reductions in colony formation ranged from 20-79%. That the colony-inhibition by lymph nodes was specific for the rat hepatoma against which lymph node donor rats had been immunized, was shown by the fact that lymph node cells from immunized mice failed to inhibit colony formation by cells of 10 tumors other than those of the original hepatoma. In similar tests, lymph nodes inhibited colony formation by target tumor cells only. Serum from tumor-immunized rats inhibited colony formation by target tumor cells, colony inhibition values ranging from 29-94%; the serum was inhibitory only against tumor cells against which the serum-donor rat had been immunized.

- 1551 INHIBITION OF IMMUNE RESPONSE AFTER TUMOR TRANSPLANTATION AND CHEMICAL CARCINOGENESIS IN MICE. (E.) Gericke, D. (Farbwerke Hoechst AG, Frankfurt, Germany), P. Chandra and A. Wacker. *Z Krebsforsch* 75(2):85-89, 1971.

Mice injected s.c. with 3-methylcholanthrene (MC, 0.05 mg/20 g body wt) were given an immunizing dose of sheep erythrocytes 7-77 days after inoculation to study the immune responses of the mice at intervals after methylcholanthrene treatment. An inhibition of plaque formation was seen 1 wk after treatment with MC; the serum plaque titers were half that of normal mice not given carcinogen. No significant inhibition of immune response was seen in treated animals 2 wk after treatment. Serum plaque formation after 0.02 mg/20 g MC remained in a suppressed state for 5 wk after treatment; twenty wk later when 3 of 6 mice had developed tumors, plaque forming cells were significantly reduced (67% of control). In another series of experiments, the immunological response after tumor transplantation was examined. Twenty-four or 48 hr after tumor transplantation, mice were injected with sheep red blood cells; inhibition of immune response was observed 48 hr after tumor transplantation, and inhibition was maximal in mice implanted with sarcoma-180, and less pronounced in melanoma. Though the immunosuppressive effects of MC were confirmed, the results did not force the conclusion that this immunosuppressive action was responsible for chemical carcinogenesis.

- 1552 RESISTANCE TO TRANSPLANTS OF RECENT SPONTANEOUS PARENTAL LINE TUMORS BY F₁ HYBRID HOSTS. (E.) Sanford, B. H. (Massachusetts Gen. Hosp., Boston) and S. F. Soo. *J Nat Cancer Inst* 46(1):95-101, 1971.

The basis for the greater resistance of F₁ hybrid hosts to strain-specific tumors was studied in experiments utilizing A/HeHa and C3H/StHa mice. F₁

hybrid hosts showed significantly increased resistance to parental tumor lines A-4, A-5, and C-9 with no difference in resistance noted in A-10 tumors; no significant sex differences were noted. Immunosuppression of the F₁ hosts by thymectomy plus irradiation significantly decreased the resistance to the A-4 and A-5 lines, while pretreatment with killed *M. tuberculosis* increased the resistance of F₁ mice. Testing the C3H lymphoma C-9, differences in response between syngeneic and F₁ hosts were found only at dosage of 5000 cells with no susceptibility shown in F₁ recipients, while 22 of 24 syngeneic hosts developed tumors. Resistance of F₁ mice could be completely abolished by immunosuppression, with all thymectomized irradiated F₁ mice developing tumors within 30 days. With ascites mammary adenocarcinoma A-10, both syngeneic and F₁ hosts reacted similarly to a variety of dosages with ascites forming by 30 days after inoculation, whereas all animals of the allogeneic C3H strain were resistant. A tumor-specific antigen of unknown nature is possibly involved here.

- 1553 IMMUNIZATION SCHEDULES FOR POTENT RABBIT ANTISERA TO LEUKEMIA L1210. (E.) Kim, C. A. H. (Tufts U. Sch. Med., Boston, Mass.) and A. E. Reif. *Cancer Res* 31(1):7-11, 1971.

The immune response which results in the production of antisera in rabbits immunized with cells of mouse leukemia L1210 cells was studied in animals given inocula of whole and disrupted cells of varying sizes and on differing schedules. Three animals were given i.v. injections of 30 million leukemia cells followed 50, 87, 89, 99, 101, 106 and 108 days later by reinoculations of the same dose. Antisera were separated into γ M and γ G fractions by gradient ultracentrifugation; γ M and γ G fractions comprised nearly the whole antiserum. The first inoculation produced a classical immune response; γ M antibody was first detected on day 4 postinoculation and showed a cytolytic potency (100/cytolytic titer) of 15, while γ G was first detected on day 8 at a cytolytic potency of 12. γ M reached maximum values on day 6 with a cytolytic potency of 8, and thereafter declined to a cytolytic potency of 8, and thereafter declined to reached maximum levels of potency (60) on day 12 and declined to a potency of (18) on day 50. Secondary immunization on day 50 and on following immunizations produced maximum potency of 35 for γ M antibody but increased the potency of γ G to 700. Subsequent immunizations increased γ G levels to 2000 by day 50 but produced diminishing γ M responses. Repeated inoculations with large doses of whole leukemia cells produced highly potent cytolytic antisera more effectively over time than did i.m. inoculation or inoculation with homogenized cells, sonically disrupted cells, or whole cells in addition to Freund-McDermott adjuvant. When reimmunization was protracted at length, evidence of immune exhaustion began to appear.

- 1554 BLOCKING EFFECT OF SERUM FROM TUMOR-BEARING ANIMALS ON MACROPHAGE MIGRATION INHIBITION WITH TUMOR ANTIGENS. (E.) Halliday, W. J. (Dept. Path., U. Washington, Seattle). *J Immunol* 106(3):855-857, 1971.

Macrophage migration from capillary tubes containing peritoneal cells drawn from mice was inhibited by extracts obtained from sarcomas induced in mice by Moloney sarcoma virus or methylcholanthrene. Peritoneal cells were prepared from mice after the regression of sarcomas induced in them by Moloney virus or after removal of tumors induced by methylcholanthrene. The peritoneal cells were incubated with tumor extracts and with serum prepared from mice with virus- or carcinogen-induced tumors. Macrophage migration was measured as the mean area of magnified migration from the capillary tube. The extract from Moloney virus-induced tumors failed to inhibit the migration of macrophage from peritoneal cells taken from mice with methylcholanthrene-induced tumors, but extracts of methylcholanthrene-induced tumors did inhibit the migration of macrophages from these peritoneal cells. Specificity of the inducing agent was also found for macrophage migration inhibition by sera from virus-induced tumor bearing mice.

- 1555 ABROGATION OF PASSIVELY TRANSFERRED TUMOR IMMUNITY *IN VIVO* BY ANTIGENICALLY RELATED TUMOR CELLS. (E.) Wepsic, H. T. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), I. D. Bernstein, B. Zbar, T. Borsos and H. J. Rapp. *J Nat Cancer Inst* 46(1):195-202, 1971.

The ability to establish passive tumor immunity was studied through systemic transfer of ascitic tumor cells from primary hepatomas in syngeneic Sewall-Wright strain-2 male guinea pigs by transfusion of peritoneal exudate (PE) cells. The ascites line-1 tumor cells in the peritoneal cavity significantly abrogated the transfer of tumor-specific immunity. In animals receiving PE cells but no tumor cells, the 7-day papule growth was $0.4 \pm 0.4 \text{ mm}^2$ following a challenge with an intradermal injection of live ascites tumor cells; in those animals which were given tumor cells 24 hr before the transfer of PE cells papule growth was similar to that of controls receiving tumor cells and was $11.0 \pm 1.6 \text{ mm}^2$. The transfer of tumor immunity was partially inhibited by the i.p. injection of ascites line-1 tumor cells before transfer but was not significantly altered by ascites line-7 cells; when ascites tumor cells were given on the same day as the transfusion with PE cells and challenged with ascites line-1 tumor cells 24 hr after transfusion of PE cells, suppression of growth of the intradermal tumor resulted. Intradermal papules did not grow in transfused, tumor-free animals, and X-irradiated line-7 cells injected i.p. had no effect on the transfer of line-1 tumor immunity. Injection (intracutaneous) of 1×10^9 X-irradiated line-1 ascites tumor cells inhibited the transfer of line-1 tumor immunity, and tumor cells mixed *in vitro* with PE cells inhibited the transfer of tumor immunity with no significant alteration in growth. Specific immunologic interaction between tumor cells and specifically sensitized cells probably accounts for survival of tumors in the face of an immune response in the host.

- 1556 THE EFFECT OF "EXOGENOUS" RNA ON THE IMPROVEMENT OF SYNGENEIC TUMOR IMMUNITY. (E.) Rigby, P. G. (U. Nebraska Coll. Med., Omaha). *Cancer Res* 31(1):4-6, 1971.

The effect of exogenous RNA treatment on survival of injected tumor cells was investigated in mice given s.c. or i.p. injections of syngeneic tumor cells and injected with RNA prepared from yeast at various times relative to tumor challenge following immunization with irradiated tumor cells. Controls given only live tumor cells had a mean survival of 19.5 days; immunization with irradiated tumor cells followed by tumor challenge produced a mean survival of 21.9 days, a difference which was not statistically significant. RNA alone, administered every other day for the 14 days before live tumor challenge or every other day for the 14 days after live tumor challenge, produced no appreciable change in mean survival times. However, when RNA was combined with the 2 doses of irradiated tumor cells and administered on day 7 and day 14 after tumor cell challenge, the mean survival time increased to 24.5 days, a statistically significant increase. When immunized mice were given RNA every other day after live tumor cell challenge, survival reached 36.1 days. The irradiated cells apparently prompted antigenic recognition in the recipients so that after live tumor cell challenge, the yeast RNA was able to produce an effective immune response to the tumor.

- 1557 EFFECT OF NORMAL TISSUE RIBONUCLEIC ACID ON A MURINE LEUKEMIC TRANSPLANT. (E.) Colmerauer, M. E. M. (Natl. Acad. Med., Buenos Aires, Argentina), C. Dosne Pasqualini and S. L. Rabasa. *Medicine* 30(5):447-450, 1970.

Mice were given i.p. injections of RNA prepared from normal mouse spleen or liver in amounts of 0.5 or 3.0 mg followed by challenge with 40 leukemia cells; RNA injections rendered mice more receptive to the leukemia cell transplant. Of 28 mice given liver RNA and challenged with tumor cells, all died within 17 days; of 30 mice given tumor cells but no RNA treatment, 14 survived, while mice which died survived for 24 days. Although 14 of 35 challenged mice treated with spleen RNA survived, there probably is no significant organ-specific difference between the transplant receptivity of mice treated with spleen RNA and that of mice treated with liver RNA. RNA apparently has an immunosuppressive effect in the mouse leukemia transplant test system.

- 1558 PROLONGED SURVIVAL OF MALE-TO-FEMALE SKIN ISOGRAFTS AND OF ALLOGRAFTS FROM NORMAL MICE FOLLOWING TREATMENT OF RECIPIENT OR GRAFT WITH SERA FROM TUMOR-BEARING MICE. (E.) Wexler, M. R. (Hebrew U. Hadassah Med. Sch., Jerusalem, Israel), M. Kripke and D. W. Weiss. *Cancer Res* 31(2):122-126, 1971.

The survival time of skin allografts derived from normal male mice and tumor-bearing mice was studied in female mice following treatment of the recipient or the graft with sera from males carrying lymphosarcoma. Skin grafts derived from donors carrying the transplanted lymphosarcoma for 24-35 days survived longer than similar grafts from normal animals or from those carrying the tumor for shorter or longer periods of time. In several instances, tumors developed at the graft sites in the recip-

ient animals or immediately adjacent to the area. Pretreatment of either the graft hosts or of the grafts with serum derived from isogenic animals carrying an implanted lymphosarcoma for 1-3 wk significantly prolonged the life of normal male skin isografts in female recipients, whereas serum obtained from animals carrying the tumor 4-5 wk was ineffective for pretreatment of graft hosts but was effective for graft incubation. Treatment of hosts with sera from tumor-bearing animals did not lead to a statistically significant shortening of the life of the graft under any of the experimental conditions used.

- 1559 QUANTITATIVE ASSESSMENT OF CELLULAR AND HUMORAL RESPONSES TO SKIN AND TUMOR ALLOGRAFTS. (E.) Canty, T. G. (Massachusetts Gen. Hosp., Boston) and J. R. Wunderlich. *Transplantation* 11(2): 111-116, 1971.

The relation between the humoral and cellular responses in the homograft reaction was studied in different lymphoid populations following skin and intraperitoneal tumor allografting across a strong histocompatibility barrier in normal and antilymphocyte-serum-suppressed adult BALB/c mice. Cellular immune activity was highest in the regional lymph nodes during the 1st wk following the challenge by skin allograft, while intraperitoneal challenge with tumor cells resulted in peak activity in the spleen and mesenteric lymph nodes. Skin graft survival times for animals pretreated with antilymphocyte serum averaged 19 days compared to 10 days for control animals receiving no treatment. Selective inhibition of cellular vs humoral immune responses in animals given a standard immunosuppressive dose of antilymphocyte serum was not demonstrable.

- 1560 INFLUENCE OF L-ASPARAGINASE ON ANTIBODY PRODUCTION AND GROWTH OF TUMORS IN ALLOGENEIC MICE. (E.) Miura, M. (Nagoya U. Sch. Med., Japan), K. Kawashima, T. Uetani, M. Hirano, H. Kakizawa, R. Ohno, A. Morita, H. Nishiwaki and K. Yamada. *Cancer Res* 31(2):114-121, 1971.

The effect of L-asparaginase on immunosuppression in several strains of mice was studied by measuring the change in production of circulating antibodies against sheep erythrocytes and allogeneic tumor cells and the incidence of ascitic leukemic tumor take in the allogeneic mice. Inhibition of primary anti-sheep erythrocyte antibody production was obtained at a dose of 25 IU of L-asparaginase/mouse, whereas 1000 IU in either single or divided doses failed to cause inhibition after rechallenge with sheep erythrocytes. Allogeneic tumor take was observed when mice were treated with more than 200 IU of L-asparaginase, but no tumor take occurred in mice preimmunized with the same tumor. The immunosuppressive action of L-asparaginase appears to affect not only the production of circulating antibody but also the cellular immunological reactivity.

- 1561 IMMUNOLOGICAL ENHANCEMENT OF MURINE TUMOR ISOGRAFTS MEDIATED BY RNA FROM LYMPHOID ORGANS OF XENOGENIC IMMUNIZED ANIMALS. (E.) Pilch, Y. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and K. P. Ramming. *Transplantation* 11(1):10-19, 1971.

RNA prepared from spleen and lymph node tissue of guinea pigs immunized with cell suspensions derived from a benzpyrene-induced sarcoma was incubated with normal mouse spleen cells and cells from the same sarcoma; this mixture was inoculated into C3H mice, and resulted in enhanced sarcoma growth. Ninety-two percent of mice given immune RNA-normal spleen and sarcoma cells developed sarcomas, the first tumor appearing 8 days after inoculation; 36% of control mice given tumor cells only developed tumors, the first of which appeared on day 25. When mice were given sarcoma cell isografts mixed with spleen cells treated with RNA from guinea pigs immunized with normal mouse tissue, tumor growth was also enhanced; however, there was a longer latency period (15 days) compared to inoculation with spleen cells incubated with RNA from immunized guinea pigs. RNA from guinea pigs immunized with Freund's adjuvant also produced tumor enhancement. Enhancement of tumor growth was specific for the immunizing tumor, since RNA from guinea pigs immunized with cells from 1 line of benzpyrene-induced tumor produced enhancement of growth for that tumor, but not for a related benzpyrene-induced tumor. Serum from mice in which enhancement of tumor growth had been produced by RNA from immunized guinea pigs markedly facilitated the growth of tumor cells incubated with this serum, suggesting the presence of an enhancing antibody in serum of mice in which enhanced growth of tumors had been produced by RNA-incubated spleen cells. No enhancement of tumor growth was produced when mice were given mixtures of tumor cells and spleen cells preincubated with RNA from guinea pigs immunized with RNase-treated benzpyrene-induced sarcoma cells. In 3 out of 5 experiments, no tumor growth enhancement was observed in mice inoculated with sarcoma cells and untreated spleen cells.

- 1562 A GROWTH-MODIFYING FACTOR FROM CELL LINES OF HUMAN MALIGNANT ORIGIN. (E.) Rounds, D. E. (Pasadena Found. Med. Res., Calif.). *Cancer Res* 30(12):2847-2851, 1970.

An attempt was made to isolate and characterize a factor which has a measurable effect on the growth and morphology of fibroblasts derived from human carcinoma cells and human embryonic skin. Cell-free culture media harvested from flasks of KB (nasopharyngeal), CMP (colon), and HeLa (cervical) cells were found to be toxic to fibroblasts derived from human embryonic skin with KB and CMP showing qualitatively greater toxicity after 48 hr. The media contained a prealbumin band in an acrylamide gel electrophoretic core, which was absent in aliquots of media that had not been used to sustain cell growth. No such band could be detected from media that had supported growth of human embryonic skin fibroblasts. Anti-

growth modifying factor (GMF) serum reacted with antigens from culture medium which had supported the established lines of KB, CMP, HeLa and amnion cells. Precipitin lines were continuous in antigens of the first three mentioned. No antigens that would react with anti-GMF serum were found from either control or nutrient fluid harvested from fibroblast cultures. Anti-human prealbumin showed a positive reaction with electrophoretically separated human serum prealbumin, but was not reactive at the same concentration with antigen derived from 48-hr cultures of CMP cells. Synthetic products from the 3 malignant cell lines were nondialyzable, showed positive reactions for peptides and proteins, were insoluble in alcohol and trichloroacetic acid and showed absorption maximum at 280 nm. Mitotic activity of fibroblasts could be stimulated and an increase in total cell number was noted with a concentration of 0.2 g/ml of CMP protein but increasing concentrations completely abolished this activity, and cell population was reduced by nearly 15%. That fibroblasts can be either stimulated or inhibited by varying concentrations of GMF could account for conflicting reports of the effects of tumor extracts on connective tissue elements.

- 1563 THE PURIFICATION AND PARTIAL CHARACTERIZATION OF A SERUM FACTOR ASSOCIATED WITH A NEOPLASM IN GOLDEN HAMSTERS. (E.) Hawthorne, C. (Dept. Zool., U. Vermont, Burlington), V. Riggs, D. F. Stevens and D. L. Weller. *Biochem Biophys Res Commun* 42(2):166-172, 1971.

A serum factor which promotes or induces cleavage in multinucleated cells in the presence of estrogen was purified from fractions of ascites fluid from ascites tumors of hamsters. The method employed permitted 5000-fold purification of the factor. Electrophoretic analysis of the fractions of hamster ascites tumors showed that the prealbumin band increased in concentration until only this band was visible in the electrophoretogram; the band showed cytokinetic activity when extracted from the acrylamide gel; sera from normal hamsters, while concentrating in the prealbumin band, did not show cytokinetic activity. The ascites serum factor concentrated on electrofocusing in the region of pH 5.5-5.8. It was suggested that the factor was a polypeptide or protein.

- 1564 γ A HALF MOLECULES: DEFECTIVE HEAVY CHAIN MUTANTS IN MOUSE MYELOMA PROTEINS. (E.) Mushinski, J. F. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Immunol* 106(1):41-50, 1971.

Two different types of γ A myeloma proteins were compared using the secretory products of two closely related tumors isolated from a single primary tumor-bearing BALB/c mouse. Ultracentrifugal analyses of the 2 γ A myeloma proteins isolated from serum showed sawtooth heterogeneity, and both exhibited different degrees of polymer formation which progressed spontaneously in solution. The mean molecular wt of 68,000 was consistent with the presence of one light chain of around 23,000 bound to a heavy chain of around 45,000 molecular wt. Completely reduced and

alkylated heavy chains of the 2 proteins were soluble in concentrated urea and guanidine HCl, and urea-Sephadex G-100 determinations yielded an average molecular wt of about 46,000 for one heavy chain (a polymeric molecule) and about 54,000 for the other (a 2-chain molecule), indicating a statistically significant difference ($p=0.0169$). Preliminary amino acid analysis showed that 5 tryptic peptides accounted for no more than 24 of the expected 80 or so amino acid residue difference between the polymeric-type heavy chain and the 2-chain forms. Direct chemical localization of the polypeptide segment present in the polymeric heavy chain and not in the 2-chain protein is being attempted.

- 1565 BIOSYNTHESIS OF THE CARBOHYDRATE PORTION OF IMMUNOGLOBULIN: RADIOCHEMICAL AND CHEMICAL ANALYSIS OF THE CARBOHYDRATE MOETIES OF TWO MYELOMA PROTEINS PURIFIED FROM DIFFERENT SUBCELLULAR FRACTIONS OF PLASMA CELLS. (E.) Melchers, F. (Max Planck Inst. Molec. Genet., Berlin, Germany). *Biochemistry* 10(4):653-659, 1971.

Myeloma proteins from the subcellular fractions of 2 mouse plasma cell tumors were assayed. Cell homogenates from the tumors (called MOPC21 and MOPC46) were fractionated by density gradient centrifugation. Centrifugation yielded 3 subcellular fractions: smooth membrane (without ribosomes), rough membrane (with ribosomes), and cytoplasmic supernatant. Myeloma protein was detected in all 3 fractions. The cytoplasmic fraction contained between 3-30% of the total intracellular myeloma protein, indicating that at least 97% of protein may be compartmentalized in membranous structures in the plasma cells. This suggested that the protein in the cytoplasmic supernatant fraction represented an artifact in the preparation of cell homogenates. The 2 types of plasma cell tumor had similar distributions of myeloma protein among their subcellular fractions; they showed similar kinetics of tritiated leucine and tritiated monosaccharide incorporation into their myeloma proteins. The subcellular distribution of ^3H -mannose, ^3H -glucosamine and ^3H -galactose in the tumors was investigated by labeling cells for 6 hr with the radioactive proteins. Myeloma protein associated with rough membrane contained glucosamine and mannose residues, but only traces of galactose and no fucose; smooth membrane myeloma proteins contained residues of glucosamine, mannose and galactose and traces of fucose. The relative amounts of mannose, galactose, glucosamine and fucose located in the 3 subcellular fractions was virtually identical in the 2 types of plasma cell tumor. The results appeared to support the hypothesis that addition of carbohydrate residues to immunoglobulins proceeds in several stages and in different areas of the plasma cells.

- 1566 FETAL GUT ANTIGEN: A SUBSTANCE IN FETAL GUT AND ITS RELATIONSHIP TO GUT CARCINOMA. (E.) Smith, J. B. (Natl. Naval Med. Ctr., Bethesda, Md.) and R. T. O'Neill. *Res Commun Chem Path Pharmacol* 2(1):1-15, 1971.

The presence in human fetal gut of an antigen, fetal gut antigen or FGA, was determined in micro double-

diffusion tests using antiserum prepared by injecting a rabbit with human fetal gut extracts. FGA was found to have an electrophoretic mobility similar to that of beta-globulins; it was found in 87% of gut extracts from human fetuses aged 10-34 wk. FGA was also found in the liver of 2 fetuses, in the lung of another and in the skin of a fourth. FGA was found in 8% of tissues from the gastrointestinal system of normal humans and in 31% of tissues from human gastrointestinal systems affected with malignancies or ulcerative colitis. FGA was not found in malignant tissues other than the gastrointestinal tract, except in tissue from a Wilm's tumor. FGA was found in 1 of 452 human serum samples studied; the serum was prepared from a patient with gastrointestinal metastases from a laryngeal carcinoma. The antigen was not found in normal fetal serum, in the serum of pregnant women, nor in the serum of patients with gastrointestinal tract malignancies.

- 1567 AN IMMUNOLOGICAL STUDY OF SOME HUMAN BRAIN TUMORS CONCERNING THE BRAIN SPECIFIC PROTEIN S_{100} . (E.) Haglid, K. G. (Inst. Neurobiol., U. Gothenburg, Sweden) and C. A. Carlsson. *Neurochirurgia* 14(1):24-27, 1971.

A method for differentiating between primary and secondary brain tumors and for indicating the origin of brain tumors has been analyzed utilizing specific protein S_{100} . Normal brain tissue and tumors originating from glial cells showed a positive reaction to anti S_{100} ; undiluted homogenates of normal brain had the most positive reaction with antiserum dilutions of 1:5 and 1:10. Those tumors showing positive reactions included astrocytomas, spongioblastomas, glioblastoma multiformes and gliomas of supratentorial, infratentorial and spinal cord origin, while negative findings were reported from ependymomas, meningiomas, adenomas, sarcomas and metastatic lesions of supratentorial and infratentorial origin. Using an immunological technique, a protein antigenically identical with the S_{100} protein was found to be present in tumors of glial origin but was missing in tumors originating from non-glial structures.

- 1568 A NEW MOUSE IMMUNOGLOBULIN: IgG3. (E.) Grey, H. M. (Natl. Jewish Hosp. Res. Ctr., Denver, Colo.), J. W. Hirst and M. Cohn. *J Exp Med* 133(2):289-304, 1971.

The structural and biologic properties of a new mouse immunoglobulin, IgG3, were studied in the J606 murine myeloma tumors by immunodiffusion, immunoelectrophoresis and radial immunodiffusion methods. The J606 protein was first identified as an immunoglobulin showing a reaction on an Ouchterlony diffusion slide with a beta 2-6-linked levan showing 1 major band on acrylamide gel electrophoresis, which showed as 2 or 3 closely running bands of decreasing intensity upon dilution. Papain digested the protein into 2 fragments which were non-crossreacting, and a single homogeneous peak was eventually obtained with a sedimentation coefficient of 5.85 upon ultracentrifugation. The intact protein had a molecular wt of 150,000, and the slow-migrating papain fragment had

a molecular wt of 47,000. After partial reduction and alkylation of J606 protein, heavy and light chains with molecular wt of 50,000 and 23,000, respectively, were separated; the heavy chain possessed 9-10 carboxymethyl cysteines after complete reduction and alkylation. Relatively high concentrations of the protein were noted in newborn mice, probably due to placental transport. This new protein was shown to be present in normal mouse serum at a concentration of 0.1-0.2 mg/ml.

- 1569 SERUM GROUP-SPECIFIC (Gc) PROTEIN CONCENTRATIONS IN PATIENTS WITH CARCINOMA, MELANOMA, SARCOMA, AND CANCERS OF HEMATOPOIETIC TISSUES AS DETERMINED BY RADIAL IMMUNODIFFUSION. (E.) Hughes, N. R. (Prince of Wales Hosp., Randwick, New South Wales, Australia). *J Nat Cancer Inst* 46(3):665-675, 1971.

An examination of sera from 1,238 samples taken from patients with cancer of 29 sites, and from 256 normal controls indicated that the mean concentrations of group-specific (Gc) protein in serum was higher in females than it was in males in both the cancer group and in controls. Female patients with malignant melanoma also showed higher mean Gc protein concentrations than males with malignant melanoma. Females with breast cancer or carcinoma of the colon and rectum also had higher Gc protein concentrations than normal males and males with carcinoma of the colon and rectum, resp. The mean concentration of Gc protein in sera from all cancer patients combined did not differ significantly from that of controls. Males with lymphatic tumors other than lymphatic leukemia, fibrosarcoma, osteogenic sarcoma, poorly differentiated sarcoma, or Ewing's tumor had higher concentrations of Gc protein than did normal males. For both controls and cancer patients, significant differences in mean Gc protein concentration were found between sera of different Gc groups; the highest Gc protein levels were found in group Gc 1:1 sera and the lowest in group Gc 2:2 sera.

- 1570 IMPAIRED *IN VITRO* RESPONSE OF CIRCULATING LYMPHOCYTES TO PHYTOHEMAGGLUTININ IN DOWN'S SYNDROME: DOSE- AND TIME-RESPONSE CURVES AND RELATION TO CELLULAR IMMUNITY. (E.) Rigas, D. A. (U. Oregon Med. Sch., Portland), P. Elsasser and F. Hecht. *Int Arch Allerg* 39(5-6):587-608, 1970.

Lymphocytes from venous blood of 9 patients with Down's syndrome and 9 healthy subjects were treated with phytohemagglutinin (PHA) in varying doses; it was found that the incorporation *in vitro* of ^{14}C -labeled thymidine into the DNA of the lymphocytes stimulated with PHA was significantly impaired in Down's syndrome patients as compared to normals. At doses of 0.001 mg of PHA/ml of culture, the incorporation of thymidine in Down's syndrome patients was consistently impaired; at this dose, the amount of thymidine incorporated by lymphocytes of patients with Down's syndrome was about 70% that of normal subjects. A minimal response of thymidine incorporation which occurred at a dose level of 0.0005 mg PHA/ml and in the absence of PHA was consistently higher in Down's syndrome patients than in normal subjects.

Dose-response studies showed that the optimal dose of PHA for maximum thymidine incorporation by lymphocytes was 0.005 mg/ml culture, which caused more than 3 times as much thymidine incorporation in normal subjects as in Down's syndrome patients. The immune deficiency suggested by the impaired lymphocyte response to PHA in Down's syndrome may be related to the high incidence of leukemia seen in patients with this condition.

1571 A ROLE FOR RED CELLS IN PHYTOHEMAGGLUTININ-INDUCED LYMPHOCYTE STIMULATION. (E.)

Tarnvik, A. (Dept. Clin. Bacteriol., U. Umea, Sweden). *Acta Path Microbiol Scand* 78(6):733-740, 1970.

The influence of various blood cell types on phytohemagglutinin (PHA)-induced lymphocyte stimulation was investigated using venous blood from healthy donors. The PHA-response of lymphocytes was measured by the *in vitro* incorporation of ^3H -thymidine by the lymphocytes. Lymphocytes prepared in cultures with the buffy coat of whole blood incorporated 85.7×10^3 cpm of ^3H -thymidine, while purified lymphocytes incorporated 37.3×10^3 cpm ^3H -thymidine; purified lymphocytes with added filtered blood cells (4×10^6 RBC/ml) incorporated 91.2×10^3 cpm radioactive label. When purified lymphocytes were incubated in the presence of varying numbers of RBC, the thymidine incorporation by the lymphocytes was dependent on the number of RBC added to the incubation mixture. Incubation of lymphocytes with mitomycin-treated monocytes and platelets also increased the incorporation of ^3H -thymidine by PHA-stimulated lymphocytes over that observed for purified stimulated lymphocytes alone.

1572 STUDIES OF THE AFFINITY OF NUCLEAR MATERIAL FOR UROPORPHYRIN: II. PHYTOHEMAGGLUTININ "TRANSFORMED" RAT PERITONEAL LYMPHOCYTES. (E.)

Hartmann, G. R. (Dept. Med., U. Minnesota, Minneapolis) and C. J. Watson. *Biochem Med* 4(5-6):403-407, 1970.

The effect of uroporphyrin on Sprague-Dawley rat mononuclear cells stimulated *in vivo* by phytohemagglutinin was studied by fluorescence microscopy. After 10 days of daily i.p. administration of phytohemagglutinin-P the rat peritoneal fluid contained many cells of the relatively large, immature or "blastic" type referred to as "transformed" lymphocytes which exhibited an affinity for uroporphyrin revealed by a distinct red nuclear fluorescence which persisted after repeated washings with normal saline or fetal calf serum. Cells aspirated prior to uroporphyrin injection exhibited no red fluorescence. Similarly, untreated rats injected with uroporphyrin failed to exhibit cellular red fluorescence. Nuclear fluorescence of the transformed cells did not increase upon addition of 0.1 N HCl, a phenomenon which is generally observed with Ehrlich ascites tumor cells even though the affinity of nuclear material for uroporphyrin paralleled the behavior of the tumor cells.

1573 EVIDENCE FOR THYMIC DEPENDENCE OF PHA-REACTIVE CELLS IN SPLEEN AND LYMPH NODES AND INDEPENDENCE IN BONE MARROW. (E.) Blomgren, H.

(Karolinska Inst., Stockholm, Sweden) and E. Svedmyr. *J Immun* 106(3):835-841, 1971.

The role of the thymus was studied during recovery of the phytohemagglutinin (PHA) response in the spleen, lymph node and bone marrow cells of mice of strains CBA and BALB/c which were lethally X-irradiated and protected with bone marrow and fetal liver cells. *In vitro* PHA response was lowest 8-10 days after irradiation in the thymus, spleen and lymph node cells and increased to values found in non-irradiated controls at 35-55 days; these values remained low in controls containing no PHA in the cultures. In contrast, the response of the bone marrow cells was high at 8 days and remained constant during the period of observation. Mice that were thymectomized 3-4 wk before irradiation showed lower reactivity in spleen and lymph node cells compared to thymectomized mice treated additionally with thymic cells or to mice undergoing sham thymectomy; bone marrow cells from all 3 groups were more or less equal. The differences in the PHA response paralleled the differences in the number of nucleated cells; comparable differences were observed when the mice were injected with fetal liver cells. Pretreatment of lymph node cells from both strains of mice with antiserum drastically reduced the response of the surviving cells, but this effect was not seen with bone marrow cells. These results indicate that the responsive cells in the bone marrow are not thymus-derived, and theta-bearing cells in the lymph nodes are mainly responsive to phytohemagglutinin. In the bone marrow a theta-negative cell population can also be activated by PHA.

1574 *IN VITRO* RESPONSES OF LYMPHOCYTES FROM CANCER-BEARING PATIENTS TO AUTOCHTHONOUS TUMOR TISSUES. (E.) Hsu, C. C. S. (Mt. Sinai Hosp., New York, N. Y.) and S. R. Cooperband. *Proc Soc Exp Biol Med* 136(2):446-448, 1971.

Tumor and normal tissues from 10 patients who underwent surgery for malignancy were incubated with blood lymphocytes from the same patient donors in order to investigate lymphocyte proliferation as a response to autochthonous tumor cells. The tumors were carcinomas from the stomach, breast and rectum. Four of 6 patients were positive when tested for the presence of intact delayed hypersensitivity. Lymphocytes from all patients showed a proliferative response to phytohemagglutinin, with large numbers of cells showing blast transformation. Incorporation of tritiated thymidine by DNA of the phytohemagglutinin-stimulated cells was relatively low. The lymphocyte responses of the patients to autochthonous tumor tissue and normal tissue were not markedly different, and no general lymphocyte response to the tumor cells could be demonstrated.

1575 STUDIES ON MALIGNANT TUMOR AND ANEMIA. X. IMMUNOLOGICAL INVESTIGATION ON MUCO-PROTEIN IN CANCEROUS URINE AND ANAEMIA-INDUCING SUBSTANCE IN HUMAN PLACENTA. (Jap.) Ogata, K. (Fac. Med. Hirosaki U., Japan). *Hirosaki Med J* 22(2):251-263, 1970.

The Ouchterlony method was employed to determine whether the mucoprotein from urine of cancer patients and the human placental anemia-inducing substance P-62 have a common antigen. Urine specimens were prepared from patients with and without malignancy and antiserum against the placental anemia-inducing substance was prepared by immunizing rabbits with complete Freund adjuvant. A characteristic precipitation was seen on gel diffusion between a fraction from cancer patients' urine and the anti-P-62 antiserum, while the same fraction from normal urine showed no reaction with anti-P-62. The locus of the precipitation was at the position corresponding to the γ M and/or the γ A-globulin regions. Apparently, the mucoprotein in urine of cancer patients does have antigen in common with the anemia-inducing substance in human placenta.

- 1576 IMMUNE FUNCTION IN MULTIPLE MYELOMA: IMPAIRED RESPONSIVENESS TO KEYHOLE LIMPET HEMOCYANIN. (E) Harris, J. (U. Texas M.D. Anderson Hosp. & Tumor Inst., Houston), R. Alexanian, E. Hersh and P. Migliore. *Canad Med Ass J* 104(5):389-393, 1971.

An investigation into the immune deficiency state associated with multiple myeloma in man was made by immunization with keyhole limpet hemocyanin (KLH) of 23 patients with multiple myeloma, 4 patients with treated localized plasmacytoma and 14 normal subjects and by evaluation of antibody formation and hypersensitivity response as well as *in vitro* lymphocyte blastogenesis. By the 7th postimmunization day, control subjects developed antibody to KLH but only 8 out of 23 of the myeloma patients showed detectable antibody which reached a peak median titer for total antibody of 4 (dilution 1-16), compared to a value of 6 (dilution 1-64) for the normal subjects. Decline in titer was noted after 14 days in the myeloma group, but the control group titers plateaued until at least 56 days after immunization. Immune responses of the plasmacytoma group were in the normal subject range. All normal subjects had developed delayed hypersensitivity to the agent by day 7 while 8 of 10 myeloma patients gave positive reactions with 2 additional subjects showing positive results on day 14. Both control and myeloma patients showed a slight but definite response *in vitro* to the agent prior to immunization with the myeloma group showing impaired response over a period of 14 days (the median response for the myeloma group was 2700 cpm compared to 6800 cpm for the controls which tended to plateau thereafter). Immunologically competent lymphocytes of both "thymus-dependent" and "immunoglobulin-producing" types are abnormal in patients with clinically overt multiple myeloma.

- 1577 COMPARATIVE STUDIES OF ANTIGENS PRESENT IN NEUROBLASTOMAS AND IN FETAL AND ADULT ADRENALS. (Fr.) Kohen, M. (Inst. Res. Sci. Cancer, Villejuif, France), D. Buffe and P. Burtin. *Bull Cancer* 57(3):355-364, 1970.

Five tissue antigens were found in soluble extracts from neuroblastomas and from human adult and fetal adrenals in an immunochemical study. None of the antigens was found to be specific for the neuroblastoma, and none were found to be specific for normal adult or fetal adrenal tissue. On electrophoretic precipitation, all the different precipitin lines produced by the antigens appeared as proteins; no evidence of lipids, glycoproteins or nucleic acids were found. Esterase activity was demonstrated for 2 of the 5 antigens. In fetal adrenals, α_1 -fetoprotein was present, but in sera from children with neuroblastomas, neither tumor specific antigen nor anti-tumor antibodies could be detected. Positive reactions were seen between some patients' sera and some antineuroblastoma antisera, but these reactions were thought to be due to a nonspecific tumor antigen, α_2 H-globulin, which was found in the sera of many of the cancer patients.

- 1578 CONCURRENT INFECTIOUS MONONUCLEOSIS AND ACUTE LEUKEMIA: CASE REPORTS, REVIEW OF LITERATURE AND SEROLOGIC STUDIES WITH THE HERPES-TYMPUS VIRUS (EB VIRUS). (E.) Stevens, D. A. (Stanford U. Hosp., Palo Alto, Calif.), P. H. Levine, S. K. Lee, M. J. Sonley and D. E. Waggoner. *Amer J Med* 50(2):208-217, 1971.

High titers of Epstein-Barr virus (EBV) antibodies were found in 2 cases of infectious mononucleosis (IM) which developed following the diagnosis of acute lymphocytic leukemia (ALL). In these 2 new cases, and in 5 previously recorded cases of concurrent IM and ALL, the elapsed time from ALL onset to IM onset was 2-45 months; in the 2 new cases, the development of IM in the course of ALL appeared to have a favorable effect on ALL. In 1 case EBV antibody titers rose from 40 prior to onset of IM to 160-2,560 following IM; and in the second new case antibody titers rose from 160 to 2,560 in 6 months following the onset of IM. Geometric mean titers anti-EBV antibody for late-stage ALL patients, pretherapy ALL patients, patients with hematologic diseases, and patients without malignant disease were similar (titers of 1:12-1:32); however, anti-EBV antibody titers for long-term ALL survivors were consistently higher than titers in the former groups (geometric mean titers of 1:161). These differences were significant only in the comparison of long-term ALL survivors with non-malignant patients and late stage ALL patients. No correlation could be shown between high anti-EBV titer and length of survival of ALL patients. In the 2 new cases of concurrent IM and ALL, a secondary rise in EBV antibody titer was seen after recovery from IM; in IM patients without ALL, EBV antibody titers fell after recovery from IM, indicating that the sustained rise in EBV antibody titer in the IM-ALL cases is due to the concurrence of the 2 diseases.

- 1579 LYMPHOCYTE INFILTRATION IN BLADDER CARCINOMA. (E.) Tanaka, T. (Sch. Med. U. Leeds, England), E. H. Cooper and C. K. Anderson. *Rev Eur Etud Clin Biol* 15(10):1084-1089, 1970.

Urinary bladder tumors were examined to investigate the extent of lymphocyte infiltration and to correlate lymphocyte infiltration with the pathological type of lesion and with the clinical course. The case material consisted of 1,090 specimens of bladder tumor from 762 English patients. Twenty-four percent of the tumors were benign lesions, including epithelial hyperplasia, cystitis cystica or glandularis, fibrosis or leukoplakia; 73% were carcinomas, 32% of which were well-differentiated, 22% were poorly-differentiated, and 18% were anaplastic. The remainder of the examined specimens included carcinoma *in situ* and carcinoma invasion from the uterus or rectum into the urinary bladder. Lymphocytic infiltration was more often seen in carcinomas than in benign lesions; diffuse lymphocytes were found in 6 benign lesions, in 40 well- and poorly-differentiated carcinomas, and in 28 anaplastic carcinomas. Survival of patients was similar in cases showing lymphocytic infiltration and in patients without infiltration. The reasons for the variations among tumors in the presence of and in the degree of lymphocyte infiltration are obscure; tumors showing marked lymphocytic infiltration may be more antigenic than other tumors.

- 1584 *IN VITRO* "SPONTANEOUS" NEOPLASTIC TRANSFORMATION OF MOUSE FIBROBLASTS IN DIFFUSION CHAMBERS. (E.) Parmiani, G. (Nat'l. Tumor Inst., Milan, Italy), G. Carbone and R. T. Prehn. *J Nat Cancer Inst* 46(2):261-268, 1971.

Muscle cells of newborn mice were placed in diffusion chambers 13 mm in diameter containing millipore filters with outside and inner porosities of 0.45 and 1.2 μ , resp. Loaded diffusion chambers were placed in a liquid culture medium or in the peritoneal cavity of syngeneic mice; at 4 wk intervals from the 8th to the 36th wk of culture, diffusion chambers were opened and the growth of the enclosed tissue was observed. At these times, fragments of muscle tissue were implanted s.c. into immunodepressed mice to test the tissue for oncogenicity. It was found that 44 of 52 diffusion chambers maintained *in vivo* within mice contained growing cells, while only 15 of 44 diffusion chambers maintained *in vitro* contained growing cells. No neoplastic transformation was evident in cells cultured in diffusion chambers maintained *in vivo*; none of the 44 mice given transplants of the tissue developed tumors for 50 wk after transplantation. However, 5 of 15 diffusion chambers maintained *in vitro* gave rise to tumors when transplanted in mice; after 20 wk *in vitro*, surviving cells from all diffusion chambers produced tumors. Tumors obtained from *in vitro* transformed tissue did not show significant antigenicity. Apparently neoplastic transformation of the cells in the diffusion chambers depended on the field medium provided by *in vitro* cultivation.

- 1585 FINE STRUCTURE OF RESERVE CELL HYPERPLASIA AND INCOMPLETE SQUAMOUS METAPLASIA OF THE UTERINE CERVIX. (E.) Laguens, R. P. (Sci. Invest. Comm. Prov. Buenos Aires, La Plata, Argentina), J. Lagrutta and F. Quijano. *Int J Gynaec Obstet* 9(2): 41-49, 1971.

Cervical biopsy specimens taken from nonpregnant patients aged 19-42 yr with reserve cell hyperplasia and incomplete squamous metaplasia of the uterine cervix were examined by electron microscopy. Columnar mucus cells of reserve cell hyperplasia patients were similar to those in normal endocervical epithelium; they had numerous microvilli, abundant cytoplasmic secretion droplets, and meager cytoplasm. Nucleoli of these cells were unusually large. Microvilli of cells touched those of nearby cells and defined irregular intercellular spaces. Mitochondria, endoplasmic reticulum and Golgi apparatus were not well developed. Cells in biopsies from patients with incomplete squamous metaplasia showed a marked polymorphism, with 3 cell types being prominent. One cell type appeared as small cells with scarce cytoplasm of high electron density, and was similar to the hyperplastic reserve cell type. The second cell type was represented by typical columnar mucus cells, and the third type appeared as large cells with abundant cytoplasm and a well-developed rough endoplasmic reticulum; these cells resembled normal endo- and exocervical cells. The hyperplastic reserve cells may be the origin of severe cervical dysplasia and carcinoma *in situ*, and their prolifer-

ation and incomplete differentiation may result in incomplete squamous metaplasia.

- 1586 MORPHOGENESIS OF EXPERIMENTAL KIDNEY TUMORS IN HAMSTERS. (Rus.) Yermolova, T. S. (Inst. Orenburg, U.S.S.R.) and L. A. Cherkasskiy. *Onkol* 16(11):55-61, 1970.

The morphogenesis of synestrol-induced kidney tumors in hamsters was investigated. Four experimental groups were used: 1) 33 male hamsters were given 2 mg synestrol s.c. once a month for 14 months; 2) 16 male hamsters were given 20 mg synestrol s.c. for 10 months; 3) 19 female hamsters received 2 mg synestrol s.c. for 11 months and 4) 25 female hamsters were subjected to ovariectomy prior to the 2 mg synestrol s.c. treatment for 8 months. Of the alterations first noticed in the kidney tissue following synestrol administration (dysproteinosis, granular dystrophy, amyloidosis), the proliferation of straight and convoluted tubular epithelial cells was most closely related to the later development of tumors. Epithelial cell proliferation was noticed in all male hamsters on the 17-20th day and in the female hamsters of group 3 and 4 on the 68th day after the beginning of the experiment. The female hamsters developed tumors. The progressive development of convoluted tubular epithelium in male hamsters led to the formation of adenomas, beginning on the 312th day in the animals of the group 1 and on the 220th day in the hamsters of the group 2. Multiple bilateral tumors appeared in 6 males of the group 1 and in 3 males of group 2 on the 321-418th day and 267-311th day, respectively. The weight of the tumor-invaded kidney varied from 400 to 5650 mg. Three hamsters showed metastasis to the spleen and diaphragm. The tumor nodules were not encapsulated and had rather diffuse boundaries. The presence of small adenomas and dispersed groups of proliferated intertubular histiocytes was also noticed.

- 1587 ONTOGENESIS AND PRECANCEROUS CHANGES OF SERUM GLOBULINS IN MICE: ESPECIALLY IN RELATION TO PATHO-MICROSCOPIC FINDINGS IN VARIOUS ORGANS. (E.) Yokota, Y. (Fac. Med. Shinshu U., Japan). *Med J Shinshu Univ* 15(1):17-46, 1970.

Serum changes occurring in normal mice of various strains following birth and in mice sensitized with a plasma-cell producing tumor antigen were investigated. The ultracentrifugation pattern of the serum of normal newborn mice showed 2 peaks of 6S and 7S. Reticulum cells were predominant in the bone marrow of normal mice, and no plasma cells could be seen. The total serum protein decreased after antigen sensitization; between 4-48 wk after sensitization, protein concentrations in the different mouse strains dropped in many cases to half their 4 wk values. Concentrations at 40-48 wk clustered around 4% for different strains. In BALB/c and C3H strain mice, 4S, 7S and 18-20S peaks were present in the serum from 8-26 wk after sensitization; after 26 wk, only 4S and 18-20S peaks were present. In sensitized mice, plasma cell infiltration was localized chiefly around the arteriolar region; infiltration increased with time after sensitization but became negligible after 26 wk postinjection.

1588 DIFFERENTIATION OF MALIGNANT TO BENIGN CELLS. (E.) Pierce, G. B. (U. Colorado Med. Ctr., Denver) and C. Wallace. *Cancer Res* 31(2): 127-134, 1971.

Rats bearing well-differentiated squamous cell carcinomas of the lip were given injections of ³H-thymidine for the purpose of observing the proportion of labeled nuclei in undifferentiated and well-differentiated tumor cells. Tumors consisted of well-differentiated tissue, with squamous pearls separated from one another by undifferentiated cancer cells. Two hr after ³H-thymidine was injected, most of the label was incorporated into the undifferentiated cancer cells, and only 5 labeled cells were found in the well-differentiated squamous pearls. By 50 hr post-injection, the number of labeled cells in the undifferentiated cells had declined markedly, and there were 56 ³H-labeled cells in the pearls. By 96 hr postinjection, the number of labeled cells in the pearls had increased to 219. Tumor growth apparently dependent on proliferation of undifferentiated cells and the growth of the pearls depended on assimilation of the undifferentiated cells into the pearl. Electron microscopy showed that undifferentiated cells which were incorporated into pearls became well-differentiated. Undifferentiated and well-differentiated cells were transplanted into compatible hosts with the result that of 82 undifferentiated cells transplanted, 27 developed into tumors in 7 months; of 78 well-differentiated pearl-cell transplants, none developed into tumors.

1589 PATHOGENESIS OF LYMPHORETICULAR NEOPLASMS IN TRANSPLANT RECIPIENTS. (Ger.) Krüger, G. (Natl. Cancer Inst., Natl. Inst. Hlth, Bethesda, Md.). *Verhandl Deutsch Ges Path* 54:175-181, 1970.

Reports of tumors in lymphoreticular tissue after organ transplantation and the associated immunosuppressive treatment led to these experiments to determine if simultaneous chronic antigen stimulation and immunosuppression can effect lymphomagenesis. Mice were subjected to immunosuppression by thymectomy, splenectomy, Imuran with and without antilymphocytic serum or Dilantin, and antigenic stimulation with LDH virus, vaccinia virus, tumor cells, complete adjuvant, HeLa cells or Dilantin. Of these combinations, only 2 (the Dilantin-Dilantin and the Imuran-antigen) showed lymphomagenesis, while the others revealed an increased proliferation of normal cells with neoplastic characteristics in some cases. The controls with only continuous antigen stimulation or with only immunosuppressive treatment led to regressive proliferative changes, but not to tumors. In the transplantation of foreign tissue the continuous antigen stimulation of the recipient and the need to suppress antibody formation result in the formation of lymphoreticular neoplasm.

1590 ARGYROPHIL CELL: HYPERPLASTIC, PRE-NEOPLASTIC AND NEOPLASTIC PROLIFERATIONS: A PRELIMINARY OBSERVATION. (E.) Soga, J. (Niigata U. Sch. Med., Japan) and T. Hatano. *Acta Med Biol Niigata* 18(1):1-6, 1970.

Behavior of argyrophil cells in human gastric and colonic carcinomatous mucosa was studied in 36 individuals by means of argentaffin reactions. In 8

of 20 cases with gastric carcinoma and 3 of 16 cases with colonic carcinoma, increased numbers of argyrophil cells close to the malignant lesions were seen primarily in the base of the glands. In the *Mastomys* gastric mucosa, argyrophil cells were observed in scattered foci of 2 or 3 cells near argyrophil cell neoplasia and appeared to be hyperplastic proliferation possibly of a reactive nature. Furthermore, normal portions of the glandular stomach bearing argyrophil neoplasms showed lesions differing from the above-mentioned; the gastric gland configuration was preserved but was completely replaced by the argyrophil cells and hence have been classified as "pre-neoplastic or pre-invasive". Further serial sections of the same portions of the stomach indicated the formation of a microneoplasm. It is postulated that the argyrophil cells in pre-neoplastic proliferation in the mucosa of *Mastomys* glandular stomach may subsequently develop into neoplastic and invasive stages followed by typical polypoid tumor formation.

1591 JUVENILE POLYPS OF THE COLON. (E.) Holgersen, L. O. (St. Luke's Hosp. Ctr., New York, N. Y.), R. E. Miller and H. A. Zintel. *Surgery* 69(2):288-293, 1971.

The pathology of juvenile polyps of the colon was investigated in a series of 55 patients, who had a total of 89 polyps of the juvenile type. These polyps were round or oval and were attached to a slender stalk; they were composed primarily of fibrous stroma usually infiltrated with acute and chronic inflammatory cells. Neither adenomatous polyps nor familial polyposis polyps were seen. No malignant potential was shown by any polyp. The age of patients with polyps ranged from 2-27 yr, with peak numbers of cases occurring in the 3-5 yr age group (7-9 cases); after age 9, there was a sharp decline in the numbers of polyp patients. Most polyps were located within the rectum. The findings fail to confirm the hypothesis that the juvenile polyp is a stage in the development of the adenomatous polyp.

1592 PATHOGENESIS OF THE MUCOSAL FOLDS ASSOCIATED WITH EARLY CARCINOMA OF THE RECTUM. (Fr.) Parturier-Albot, M. (Hotel-Dieu, Paris, France) and G. Albot. *Sem Hop Paris* 47(8):485-493, 1971.

Certain deformities of the mucosa around cancers of the rectum are described, which may be useful in determining malignancy at an early stage. The most important perilesional modifications for early diagnosis resembled those seen in small gastric cancers, with rigid sections presenting the classical aspects of infiltration, encystment, and areas of semi-rigid texture. These modifications, however, were not due to the tumor formation but to a concomitant sclerosis of the submucosa and were thought to be responsible for the appearance of abnormal folds in the mucosa, the granular character of the mucosa, and irregular folds, either thickened or containing polypoid features. Aside from the classical proctological examination by means of endoscopy, biopsy specimens were examined by serial section, and it was possible to demonstrate that as the tumor developed the early signs disappeared. The early signs

were considered to be due to vasomotor disturbances and related to contractions of the muscular mucosa.

- 1593 MALIGNANT NEURINOMAS OF THE GASTROINTESTINAL TRACT: REMARKS ON THEIR PATHOGENESIS. (Ger.) Köthe, W. (Path. Inst. U. Heidelberg, Germany). *Äertal Forsch* 25(1):20-26, 1971.

Solitary malignant neurinomas are described in 4 cases and problems related to histogenesis are considered. The first case was characterized by a tendency to infiltration with small variations in the nuclear size and rare mitoses; the second, by a regression in polar structure (Type Antoni A); the third again showed typical histological structures of Type Antoni A, with a tendency for tumor infiltration; and case 4 represented the highest degree of change including infiltration and necrotic formation. The malignant neurinomas appeared to originate from Schwann cells and the peri- and endoneural fibrocytes had a common Schwann-like mother cell, which later can become the matrix for tumor cells if their maturation is disturbed or inhibited, as is characteristic of von Recklinghausen's disease. In the malignant neurinomas tissue structures similar to those in von Recklinghausen's disease, were found. Well-differentiated Schwann cells were found in the Antoni A type polar structures, and were less differentiated in the reticular tissue.

- 1594 PATHOGENESIS OF EXPERIMENTAL HORMONE-PRODUCING OVARIAN TUMORS. (Rus.) Sheykin, P. I. (Med. Inst. Donets, U.S.S.R.). *Vop Onkol* 16(11): 48-54, 1970.

The administration of chorionic gonadotropin to random-bred rats following a single exposure of irradiation (1000 r) produced no effects on ovarian tumor incidence, latency period or morphology. The hormone was injected s.c. (100-150 U/rat) for 5 days a week over a 1-9 month period starting 3, 9 or 13 months following radiation exposure. The incidence of ovarian tumors (first occurring 11 months after radiation exposure) was 62% with respect to surviving rats and 12% with respect to the initial number of 435 rats. Androblastomas were the most frequently occurring tumors, with an incidence of 49% among the irradiated rats and 62% among the gonadotropin-treated rats. Luteomas occurred in 19% of the irradiated and in 14% of the hormone-treated rats. Thecal and granular thecal cell tumors were noticed along with the luteocellular neoplasms. Chorionic gonadotropin exhibited no luteotropic effects on the development of ovarian tumors which indicates that the intraovarian endogenous factor is more important in all the stages of the neoplastic process.

- 1595 CANCEROUS AND PRECANCEROUS STATES OF THE CERVIX UTERI: A HISTOLOGICAL AND HISTOCHEMICAL STUDY. (E.) Stenback, F. (Dept. Path. U. Oulu, Finland), A. Ojala and A. Vehaskari. *Acta Obstet Gynec Scand* 49(4):389-397, 1970.

Histochemical features of the transition from non-malignant to invasive malignant states of the cervix

uteri were investigated in 100 unselected biopsy specimens; specimens were examined for the presence of 13 chemical substances, and 27 additional specimens were examined for the presence of 9 enzymes. Specimens were classified as normal, dysplasia grade 1, dysplasia grade 2, carcinoma *in situ*, invasive well-differentiated carcinoma, and anaplastic carcinoma. As compared to normal cervical tissue, dysplasia grades 1 and 2, and carcinoma *in situ* showed relatively slight glycogen staining; well-differentiated and anaplastic carcinoma also showed decreased stainability of glycogen. Stainability of RNA was higher in dysplasia grades 1 and 2 than in normal tissue, and higher in carcinoma *in situ* and well-differentiated carcinoma than in dysplasia. Anaplastic carcinoma showed stainability of RNA comparable to that of dysplasia grade 1. Lactate dehydrogenase activity also increased with increasing malignancy and was maximal in well-differentiated carcinoma, lower in anaplastic carcinoma, and minimal in normal tissue. The histochemical changes reflected a disturbance in the normal differentiation of cells from basal to parabasal and superficial cells; the production of abnormal cell forms tending to pathological keratinization was also seen to accompany increasing malignancy.

- 1596 CYTOLOGICAL FEATURES OF PRECANCEROUS CONDITIONS AND CANCER OF THE UTERINE CORPUS. (Rus.) Kazanova, L. I. (Inst. Exper. and Clin. O Acad. Med. Sci., U.S.S.R.), V. I. Peskova and A. Kurbanova. *Lab. Delo* 12:733-737, 1970.

The cytological features of endometrial cells in uterine cancer, recurrent hyperplasia or endometrial polyposis were investigated in 44 patients (31 with uterine cancer and 13 with glandular hyperplasia or endometrial polyposis) 33-78 yr of age. Small average size cells with well-defined boundaries and round or oval central nuclei were seen in polyposis; chromatin was regularly distributed and Barr bodies were found in 30-40% of the cells. Enlarged cells with oval, round or rod-like nuclei with well-defined membranes were observed in hyperplasia; chromatin was regularly distributed within the nucleus, and 8 of 10 patients had Barr bodies in 24-42% of the tumor cells. Preparations from patients with recurrent hyperplasia of the endometrium showed polymorphic cells with oval or prismatic nuclei and regular chromatin distribution; intense epithelial proliferation with considerable cell atypia was observed and was considered to be an early stage of malignancy; Barr bodies were found in 15-17% of the cells. Fifteen of 31 cancer patients had Barr bodies in more than 20% of the cells and 11 had Barr bodies in 10-19% of the cells. 5 patients had sex chromatin-negative tumors (sex chromatin was present in less than 10% of the cells). The latter tumors consisted mainly of anaplastic while all sex-chromatin-positive tumors appeared to be adenocarcinomas.

- 1597 CLUES TO THE POSSIBLE MODE OF ACTION OF CIGARETTE SMOKE IN THE PATHOGENESIS OF CANCER. (E.) Malhotra, S. L. (Med. Dept., South Railway, Garden Reach, Calcutta, India). *J Indian Med Ass* 55(8):265-270, 1970.

Tobacco smoke from various sources, including cigarettes, pipes, and cigars, was tested to determine whether, and in what degrees, smoke from each source neutralized HCl and NaOH; the results were discussed in relation to possible etiological factors for human lung cancer. It was found that tobacco smoke did not neutralize HCl, and that pipe smoke was more acidic than cigarette or cigar smoke. The amounts of tobacco smoke neutralized by 0.32N NaOH were 7.3, 6.9, 5.3, 4.7, 1.6 and 2.1 ml, resp., for 6.7 g of cigarette paper, pipe, Indian *biris*, cigar, unfiltered cigarettes, and filtered cigarettes, resp. Pipe tobacco smoke was found to contain more CO₂ than did smoke from other tobaccos. These findings correlated with changes of the respiratory epithelium thought to result from the action of weakly acidic smoke, such as loss of intracellular mucus from epithelial tissues leading to inflammatory and proliferative changes in the mucosa. These effects of cigarette smoke on intracellular mucus were thought to be more pronounced in persons with unusually high numbers of mucus-bearing goblet cells, and less pronounced in persons with fewer goblet cells and more non-mucus-bearing ciliated cells.

- 1602 CANCER STATISTICS, 1971. (E.) Silverberg, E. (Amer. Cancer Soc., New York, N. Y.) and A. I. Holleb. *CA* 21(1):13-31, 1971.

Changes in recording, classifying and compiling cancer mortality statistics since 1914 are discussed, emphasizing the particular problems of data interpretation which these changing policies have created. Figures for estimated 1971 cancer deaths adjusted for sex and site are presented together with estimated 1971 figures for cancer incidence for sex and site. Statistics from 1967 on cancer death rates for various sites among males and females in the United States and statistics on trends in age-adjusted cancer death rates from 1950-1952 and from 1965-1967 are reported. Estimates for 1971 by state for cancer deaths for all sites and global age-adjusted death rates from cancer of all sites from 1964-1965, are included.

- 1603 ACUTE CHILDHOOD LEUKEMIA: EPIDEMIOLOGIC STUDY BY CELL TYPE OF 1,263 CASES AT THE CHILDREN'S CANCER RESEARCH FOUNDATION IN BOSTON, 1947-1965. (E.) Fraumeni, J. F. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), M. D. Manning and W. J. Mitus. *J Nat Cancer Inst* 46(3):461-470, 1971.

Forty-four percent of 1,263 children under 15 yr with acute leukemia had lymphocytic leukemia, 24% had undifferentiated leukemia, 24% had myelogenous leukemia, and 8% had monocytic leukemia. More boys than girls had acute leukemia generally; lymphocytic and undifferentiated leukemia had maximal incidences at age 3-4 (120 and 60 cases, resp.). Monocytic leukemia had its maximal occurrence at less than 1 yr-of-age, and declined in incidence thereafter. Lymphocytic and undifferentiated leukemia declined in incidence after age 4-5 yr; after age 9 the predominant type of leukemia was myelogenous. Survival was most prolonged for children with lymphocytic leukemia (33 months after diagnosis), and shortest for children with monocytic leukemia (13 months after diagnosis). Down's syndrome occurred in 14 of the 1,263 children, which is 7 times in excess of that for the larger society. The excess of Down's syndrome was associated with all cellular types of leukemia. Other congenital defects observed in the childhood leukemia patients included Fanconi's anemia, Marfan's syndrome, and familial ectodermal dysplasia. There were 28 twins among the leukemia patients; 1 set of male twins had monocytic leukemia. Two pairs of male sibs (non-twin) had lymphocytic leukemia.

- 1604 CATS AND CHILDHOOD LEUKEMIA. (E.) Bross, I. D. J. (Roswell Park Mem. Inst., Buffalo, N. Y.) and R. Gibson. *J Med Exp Clin* 1(3):180-187, 1970.

Three hundred families in which a case of childhood leukemia had occurred and 831 randomly-selected families were examined to determine whether exposure to cats was causally related to childhood leukemia. Relative risk of leukemia associated with exposure to each of 15 animals was estimated, with the result that the relative risk associated with cats was 1.35; maximum relative risks were associated with geese (1.80), and minimum risks were associated with guinea-

pigs (0.81). Cats were the only animal with relative risk significantly exceeding 1 which were associated with a large number of leukemia cases; 117 leukemia cases were recorded as having been exposed to cats (38.1% of leukemia cases). Thirty-one percent of normal families were recorded as having been exposed to cats. More leukemia cases had been exposed to or dead cats than controls; 13% of children aged 1 yr with leukemia had been exposed to sick or dead cats compared with 6.5% of control children. The age-adjusted relative risk of leukemia development for children exposed to sick or dead cats was 2.24. These results were thought to provide evidence that exposure to cats, especially to sick cats, may be a causal factor in the development of leukemia in children. However, only about 1 case of childhood leukemia in 100,000 appeared to be accounted for by exposure to cats.

- 1605 THE EPIDEMIOLOGICAL IMPORTANCE OF CHILDHOOD CANCERS. (E.) Stewart, A. (Dept. of Med., U. Oxford, England) and R. Barber. *Brit Med Bull* 27(1):64-70, 1971.

Contributions to the understanding of carcinogenesis made by the Oxford Survey of Childhood Cancers are described. The Survey has collected data indicating that prenatal X-irradiation is associated with a general hazard of cancer development of various sites, and is not confined to an increased risk of leukemia development. A national increase in leukemia mortality in England and Wales in 1950-1959 did not affect children under 2 yr-of-age to the degree that it affected older children; there were 65 leukemia deaths/10⁶ children aged 3 yr and only 28 deaths/10⁶ children aged 2 yr. The relatively low incidence of leukemia deaths in children under 2 yr-of-age was thought to be due to the long latent period for leukemia (3-6 yr); it was also suggested that a decline in the death rate from pneumonia among children might have produced an apparent rise in the mortality rates from other conditions, including leukemia. The survey showed that children are more cancer prone than young adults, casting doubt on the accepted theory that cancer susceptibility increases with age from birth. The discovery that prenatal diagnostic X-irradiation had different carcinogenic effects postnatal irradiation (e.g., atomic bomb irradiation) may indicate that "the cell conversion phase" of the cancer process is achieved more easily than the first step in the cell-multiplication phase, phase.

- 1606 DEATHS FROM CHILDHOOD LEUKEMIA AND SOLID TUMORS AMONG TWINS AND OTHER SIBS IN THE UNITED STATES, 1960-1967. (E.) Miller, R. W. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Nat Cancer Inst* 46(1):203-209, 1971.

Cancer mortality among twins and other sibs was surveyed from 1960-1967 in the United States. Several pairs of identical twins were found to have died of leukemia in this period; in the case of all but 1 of the twin pairs, the deaths were separated by less than 8 months and occurred in the first 6 yr of life. The concordance rate for leukemia in

twins was therefore maintained at about 17%. Eight brain tumors were found among non-twin sibs (as opposed to 0.9 expected cases). Leukemia among non-twin sibs was not concentrated in the first 6 yr of life and did not affect both sibs at the same age. There were 8 families in which 1 sib died of brain tumor and another of cancer of the bone or muscle. In 2 families, 1 sib had adrenocortical carcinoma and another had rhabdomyosarcoma, a combination which may represent part of a familial cancer syndrome. Of 3 sibs with lymphoma and 1 with lymphocytic leukemia, each had sibs with carcinoma of the colon; in 1 case, the colon cancer was associated with polyposis. Wilm's tumor, lymphoma, and neuroblastoma were also recorded for sib sets.

1607 HODGKIN'S DISEASE IN ENGLISH AND AFRICAN CHILDREN. (E.) Burn, C. (Albany Med. Coll., N. Y.), J. N. P. Davies, O. G. Dodge and B. C. Nias. *J Nat Cancer Inst* 46(1):37-41, 1971.

The distribution of symptom types of Hodgkin's disease in children from 3 East African countries and from the Manchester, England vicinity were compared. African children had a significantly higher incidence of the lymphocytic depletion type of Hodgkin's disease than did the English children. Eight percent of Manchester male children and 12% of Manchester female children had lymphocytic depletion compared to 34% of African males and 57% of African females. In Manchester, there were 37 male cases and 16 female cases, while in Africa there were 112 male cases and 21 female cases. African children also had a higher proportion of lymphocytic depletion lesions than children studied from France and from Texas.

1608 CANCER IN AFRICA. (E.) Cook, P. J. (U. Coll. Hosp. Med. Sch., London, England) and D. P. Burkitt. *Brit Med Bull* 27(1):14-20, 1971.

The incidence of carcinoma in 7 selected sites in Negro populations in Africa south of the Sahara was investigated. Primary cancer of the liver was found to be the most common of all forms of cancer, representing 10-30% of all tumors in males throughout sub-saharal Africa. Its frequency in Africa is as much as 1000 times higher than its frequency in Europe. Dietary aflatoxins may be an etiological factor for liver cancer in Africans. Esophageal cancer shows more local variation of frequency than any other tumor in Africans, being rare in West Africa and very common in parts of East and South Africa. Heavy use of alcohol in which nitrosamines may be present is implicated in the incidence of cancer of the esophagus in Africa. Stomach cancer is frequent in western Kenya, and rare in northern Uganda; there may be a correlation between the high incidence and altitude. Cancer of the penis is of low frequency in East Africa where circumcision is traditional, and of high frequency west of the Kenya-Uganda border where circumcision is uncommon. Cancer of the cervix uteri is the commonest cancer in females in tropical Africa, representing 20-40% of all tumors in most series. The frequency of this condition is far higher in Africa than in western Europe and North America. It

is widespread throughout sub-saharal Africa. Kaposi's sarcoma is almost confined to Africa, representing almost 16% of male tumors in East Africa. Areas of high concentration include western Uganda. Bladder tumors are especially common in Malawi, where they represent more than 18% of all female tumors. Evidence exists for an association between cancer of the bladder and urinary bilharziasis. The development of epitheliomas on scars left by tropical leg ulcers is common in Africa and showed little regional variation in distribution. Burkitt's lymphoma distribution in Africa may be correlated with rainfall and temperature and may involve an insect vector tentatively identified as the mosquito which transmits malaria. The rarity of intestinal cancer in Africa mirrors its rarity in other underdeveloped rural areas, and may be related to cellulose content of the local diets.

1609 RACIAL VARIATIONS IN TUMOR INCIDENCE IN UGANDA. (E.) Templeton, A. C. (Dept. Path., Makerere U. Coll., Kampala, Uganda) and O. A. C. Viegas. *Trop Geogr Med* 22(4):431-438, 1970.

The incidence of cancer at various sites was determined for the African, Asian and European population groups in Uganda. While age-specific incidence rates rose for all 3 populations with age, the incidence of malignant disease dropped off in Africans at the age of 70 yr, while in Asians and Europeans it continued to rise after this age. Cancer of the oral cavity was seen most often in Asians (5.7% incidence); the high incidence of this condition may have been related to the Asian habit of chewing betel and tobacco. Asians and Europeans had higher rates of cancer of the colon, rectum and anus than Africans, possibly due to dietary differences between the Africans and the other groups. The incidence of liver cell carcinoma was higher in Africans than in the others; aflatoxin consumption may be responsible. Asians and Europeans in Uganda had higher incidences of bronchial carcinoma than did Africans; cigarette smoking and industrial pollution were thought to be the relevant etiological factors. Europeans had the highest rates of mammary cancer, and Africans had the lowest rates. Ugandan Africans had higher rates of cervical cancer than Ugandan-resident Asians or Europeans. Europeans had a markedly higher incidence of skin cancer than Africans or Asians in Uganda; exposure to sunlight was thought to be importantly related to cancer of the skin. Asians had higher rates of leukemia than Africans or Europeans. In general, environmental factors were thought to be more important than genetic factors in determining the differential rates of cancer in the 3 Ugandan populations under study.

1610 EPIDEMIOLOGY OF ASBESTOS CANCERS. (E.) Wagner, J. C. (Llandough Hosp., Penarth, Glamorgan, Wales), J. C. Gilson, G. Berry and V. Timbrell. *Brit Med Bull* 27(1):71-76, 1971.

The correlation between bronchial and pleural cancer and occupational exposure to asbestos was investigated in a survey of the literature from several countries. Mortality rates from chrysotile-mining

areas in Rhodesia and Swaziland do not show excesses in mortality from pleural or bronchial cancer; however, in the Cape Province where crocidolite is mined, significant excesses of pleural and peritoneal mesothelioma have been recorded for people living and working near the asbestos mines. In Britain, all groups of mesothelioma with case controls showed significant association with exposure to asbestos; decreases in risks of bronchial cancer have been shown to coincide with increasingly effective dust-control measures in British industries using asbestos. Similar findings have been reported from the United States. In Quebec, asbestos mining (chrysotile) has not been found to involve increasing incidence of mesothelioma. Small increases in mortality from bronchial cancer have been found for anthophyllite and other asbestos miners in Finland and Sweden. In general, it appears that an association between asbestos exposure and bronchial cancer and mesothelioma of the pleura and peritoneum is well established. The risk of bronchial cancer seems to be more clearly related to the intensity of past exposure and to the risk of asbestosis. Cigarette smokers who are exposed to asbestos are at much higher risk of developing bronchial cancer than are nonsmokers. Mesothelioma is less clearly related than bronchial cancer to dose of asbestos exposure.

- 1611 EFFECT OF CIGARETTE SMOKING ON CONNECTICUT RESIDENTS. (E.) Christine, B. W. (Conn. St. Hlth. Dept.) and P. D. Sullivan. *Connecticut Hlth Bull* 85(1):23-28, 1971.

The incidence of malignant diseases associated with cigarette smoking in Connecticut was investigated. Heart disease and cancer, the leading causes of death in the state as in the nation, have accounted for increasing numbers of deaths in recent yr. The rate of deaths from heart disease in 1925 in Connecticut was 179.1 deaths/100,000 population and 336.6/100,000 in 1969. Cancer of the respiratory system in Connecticut had an incidence of 14 cases/100,000 in 1935 among males and 70 cases/100,000 in 1970; among Connecticut females, the increased incidence has not been marked, with the incidence/100,000 cases being 5 in 1935 and 9 in 1970. Cancer (all sites) accounted for 272 deaths among Connecticut residents in the 25-44 yr age group in 1969 and 1,843 and 2,894 deaths in the 45-64 yr and 65 yr age groups, resp. Cancer of the larynx has shown a steadily increasing percentage of cases in males (66.4% in 1965 and 71.9% in 1966). Males in Connecticut have also showed increasing rates for cancer of the esophagus and bladder, which are 2 other sites of cancer thought to be causally related to cigarette smoking.

- 1612 CANCER OF THE LIP IN CONNECTICUT, 1935-1959. (E.) Shedd, D. P. (Roswell Park Mem. Inst., Buffalo, N. Y.), C. F. Von Essen, R. R. Connelly and H. Eisenberg. *Cancer Bull* 22(6):116-120, 1970.

The incidence and pathology of cancer of the lip in Connecticut residents was investigated in a survey of 1,255 patients. Men comprised 1,178 of the patients, and 1,089 of these showed involvement of the lower lip. Thirty-nine percent of women with

lip cancer had involvement of the upper lip. The mean age at diagnosis was 64 yr for men, and 67 yr for women. The incidence of lip cancer among men increased steadily with age; numbers of cases/100,000 population for men aged 40 and 55 yr were 4 and 10, resp. For women, numbers of cases/100,000 population at ages 40 and 55 yr were 0.5 and 1, resp. Eighty-one percent of lip cancer cases were diagnosed as squamous cell carcinoma. Six men and 2 women presented with carcinoma *in situ*, but most patients were in the stage of disease in which the cancer was active but localized to the lip. The 5 yr survival rate for all lip cancer patients was found to be 86%. Men with lip cancer were found to have a survival advantage over women.

- 1613 A STUDY OF LEUKEMIA WITHIN THE WEST GERMAN ARMED FORCES. (E.) Altwein, J. (Inst. Path. West German Armed Forces, Olpenitz), U. B. Mairose and K. W. Wegner. *Milit Med* 136(3):238-241, 1971.

The incidence, mortality and pathology of leukemia were investigated in the Army of the German Federal Republic between the yr 1956-1969, during which time there were 66 deaths from leukemia. The subjects ranged in age from 18-60. Mortality from leukemia ranged from 0 deaths/100,000 military personnel in 1956 and 1957 (when the Army was of limited size) to 3.2 and 2.5 deaths/100,000 in 1960 and 1969, resp. Frequency of leukemia was highest in the 20-25 yr group with peaks at the age of 21 yr (9 cases); a lower peak was recorded for the 55 yr group (3 cases). Fifty percent of acute leukemias were diagnosed within 1 month from the onset of symptoms, and 2 months thereafter 50% of the patients were dead. Possible etiological factors in leukemia cases revealed by case histories included exposure to radioactive material for 3 yr, and exposure to dimethylformamide and polyacrylonitrile. One patient's sister had chronic myelogenous leukemia. Leukocytosis of above 100,000/mm³ was observed in 25% of the patients at the time of hospital admission, but 33% showed normal or near-normal leukocyte counts.

- 1614 MELANOMA IN UTAH. (E.) Cowan, L. B. (Salt Lake City, Utah), C. R. Smart and V. Moslander. *Rocky Mountain Med* 68(1):29-32, 1971.

The incidence of melanoma in the state of Utah was surveyed for the period 1957-1970. In that time, there were 282 cases of melanoma recorded in the state, including 54% males and 46% females. Ninety eight percent of cases were among Caucasians (the Negro population of Utah is negligible). While only 15 cases of melanoma were reported in 1957-1958, 90 cases were reported in 1968-1969; the increase probably represents the increased efficiency of the central cancer registry serving 5 western states including Utah. Thirty-six percent of the melanomas affected the limbs, 31% affected the head and neck, and 21% affected the trunk. Melanoma was found to be rare in childhood, and its frequency increased with puberty and reached maximum levels at 50-55

yr-of-age. Five-yr survival figures indicated that 70% of patients with localized melanoma survived for 5 yr from diagnosis; 41% of patients with regional disease survived for 5 yr.

1615 A NOTE ON THE INCREASED RISK OF POLYCYTHEMIA VERA IN JEWS. (E.) Modan, B. (Tel Hashomer Govt. Hosp., Israel), H. Kallner, D. Zemer and C. Yoran. *Blood* 37(2):172-176, 1971.

The incidence of polycythemia vera among Jews born in Israel and Jews born in Africa and Asia was investigated in the Israeli population. Records of polycythemia vera from the period 1955-1966 revealed 155 newly diagnosed cases of definite polycythemia vera and 27 probable cases. The mean annual incidence yielded by these figures was 6.7 cases/million (7.8 including probable cases). The male:female ratio was 1.1:1; however, after the age of 50 yr, incidence was higher among females. In both sexes, there was a peak incidence in the 60-69 yr age group. In both sexes, incidence of polycythemia vera was markedly higher in European-born Jews than in Asian-African born Jews; among males aged 60-69 yr, European-born Jews had an incidence of 37.3/million, while Asian and African-born Jews had an incidence of 11.1/million. The reason for the relatively high incidence of polycythemia vera among European-born Israeli Jews is unclear.

1616 BILIARY CANCER AMONG SOUTHWESTERN AMERICAN INDIANS. (E.) Rudolph, R. (U. Hosp. Cleveland, Ohio), J. J. Cohen and R. H. Gascoigne. *Arizona Med* 27(10):1-4, 1970.

The incidence and pathology of biliary tract cancer among American Indians in New Mexico was investigated. Carcinoma of the gallbladder was found in 35 cases and cancer of the extra-hepatic bile ducts in 7 cases of 748 operations performed on the gallbladder and/or bile ducts. These findings yielded incidences for gallbladder cancer and ductal cancer of 4.5% and 0.9%, resp., which are well in excess of the figures found for the population at large, which have been estimated at 2% for gallbladder cancer and 0.5% for duct cancer. Cancer of the bile ducts and gallbladder comprised 9% of all digestive system malignancies for the New Mexico Indian population. The average age of gallbladder cancer patients was 67 yr and 64 yr for ductal cancer. In the former group, there were 9 men and 26 women; in the latter, there were 4 men and 3 women. Thirty-five patients were Navajos, 6 were Zunis, and 1 was Hopi. Adenocarcinoma was the pathologic diagnosis in all cases; the most consistent blood chemistry finding for the patients was a prothrombin time exceeding 13-14 seconds; the second most frequent feature was an elevated bilirubin. The proportion of gallbladder cancer patients surviving 5 yr after diagnosis was 9%.

1617 REGIONAL CONVERGENCE OF CANCER MORTALITY RATES OVER TIME IN THE UNITED STATES, 1940-1960. (E.) Waggoner, D. E. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and G. R. Newell. *Amer J Epidemiol* 93(2):79-83, 1971.

Regional variation in cancer mortality was investigated to pursue an earlier finding that cancer mortality was negatively correlated with environmental temperature. A general stability of high correlation between mortality and temperature through 2 decades was observed, with 3 exceptions. Cancer of the respiratory system showed a decreasing relationship with temperature; the high negative correlation in men for leukemia mortality and temperature appeared to have declined, and a low positive relationship with temperature was found in females. Finally, a continued negative correlation was found between temperature and buccal cavity and pharyngeal cancer for males. In all cancer sites, the relative variance among regions decreased from 1940-1960. Regions with relatively low site-specific death rates showed the largest percent increases in mortality rates from 1940-1960. Regional cancer rates in some parts of the nation appear to be converging toward overall national levels.

1618 BREAST CANCER IN AN AREA OF HIGH PARITY: SAO PAULO, BRAZIL. (E.) Mirra, A. P. (Central Cancer Registry, Sao Paulo, Brazil), P. Cole and B. MacMahon. *Cancer Res* 31(2):77-83, 1971.

The correlation of risk of developing mammary cancer with age at first pregnancy and with other variables was studied in a survey of 536 cancer cases and 1550 controls in Sao Paulo, Brazil. A statistically significant relationship was found between high risk of developing breast cancer and schooling; women with no schooling had a risk of 1.0, while women with 8-11 yr of schooling had a risk of 1.8. Women who had their first pregnancy before the age of 20 yr were found to have only about 2/3 the risk of developing breast cancer incurred by women whose first pregnancy had occurred at the age of 25 yr or later; a protective effect in both groups was observed for each parity level, indicating that the association of mammary cancer risk with age at first pregnancy was not merely a reflection of the well-known phenomenon of low cancer risk for women of high parity. The protective effect of early pregnancy was confined to women under the age of 50 yr. A correlation between risk of contracting breast cancer and increasing wt or wt/height index was seen in women above 50 yr. The relative risk of mammary cancer was 1.6 for women over 50 weighing 55-64 kg and 2.5 for women over 50 weighing over 75 kg. There was no appreciable difference in lactation patterns between cancer patients cases and controls.

1619 CANCER MORTALITY: PERSPECTIVES AND GYNECOLOGIC CANCER. (E.) Floyd, W. S. (Sinai Hosp., Detroit, Mich.). *Bull Sinai Hosp Detroit* 19(1):19-21, 1971.

The incidence in the United States of female genital cancers was discussed. Cancer is the leading cause of death among women aged 35-70, with 24,000 cancer deaths in this age group estimated to have occurred in 1970. Of these deaths, 9,400 will result from cancer of the cervix uteri, 3,500 from cancer of the corpus uteri, and 10,000 from ovarian cancer. The Papanicolaou smear test has reduced

the mortality from uterine cancer by 50% during the past 25 yr; however, the death rate for cancer of the ovaries has more than doubled in the past 30 yr (from 3.5 deaths/100,000 females in 1930 to 10 deaths in 1970). An increased use of cytologic screening might further improve the mortality from female genital cancers.

- 1620 FACTORS RELATED TO PROGRESSION OF CERVICAL ATYPIAS. (E.) Hulka, B. S. (Sch. Publ. Hlth., U. North Carolina, Chapel Hill) and C. K. Redmond. *Amer J Epidemiol* 93(1):23-32, 1971.

The probability of progression from an atypical cytological cervical cancer smear to a more serious cytologic and histologic status was investigated in a cervical cancer screening program involving 402 women with atypical smears on initial screening and 168 women with atypical smears on a subsequent screening. The probability of progression from an atypical smear discovered on first screening to a more serious condition was found to be greatest in the first 6 months after the first diagnosis of cytological atypia, the probability of progression during this period amounting to 13.6%. After 1 yr following initial discovery of atypia, the probability of progression remained constant and was approximately 3-4% in each 6-month interval. The cumulative probability of progression during the first 5 yr after initial screening was 41.2%. The highest probability of progression for an atypical smear taken on the 2nd to the 5th screening was recorded during the first 6 months after the finding of the initial atypia and amounted to 7.7%. The cumulative probability of progression for these smears reached its maximum in 2½ yr (17.6%). The semi-annual progression rates for smears discovered to be atypical on first screening was about half that of smears discovered to be atypical on subsequent screenings. Among women less than 30 yr-of-age, whites had a greater probability of progression than Negroes. Generally, progression rates were high among women 30-44 yr, and low in Negroes below 30 yr. Two other variables found to have some association with progression among white women were numbers of pregnancies and numbers of deliveries; increasing numbers of either were associated with increased progression rates, but not to the degree of statistical significance.

- 1621 INCIDENCE OF MULTIPLE PRIMARY CANCERS: IV. CANCERS OF THE FEMALE BREAST AND GENITAL ORGANS. (E.) Schottenfeld, D. (Mem. Hosp. Cancer Allied Dis., New York, N. Y.) and J. Berg. *J Nat Cancer Inst* 46(1):161-170, 1971.

The incidence of multiple primary cancers of various organs in women with carcinomas in the breast or genital organs was investigated in a survey of 9,792 breast cancer patients and 4,363 cases of cancer of the genitalia. Among the breast cancer patients, there were 58 synchronous and 248 metachronous primary cancers in the opposite breast, yielding an incidence of 6.1 metachronous primary cancers in the opposite breast/1,000 patients/yr. This incidence was 4.5 times the expected incidence of metachronous primary

opposite breast malignancies. Among women with carcinomas of the breast, the incidence of multiple primary cancers in the ovary was 0.6/yr/1,000 patients. This incidence was only 1/10 of the risk of developing opposite breast malignancies, but was twice the expected risk of developing ovarian cancers. Among women with primary ovarian cancers, the incidence of metachronous primary breast cancers was 5.3/yr/1,000 patients, or 4.4 times the expected rate. The observed number of subsequent cancers of the corpus uteri was less in women with primary breast carcinomas than in women with ovarian cancers. Among women with primary cancers of the corpus uteri, the incidence of breast cancers was 3.2/yr/1,000 patients, or 2 times the expected rate. The risk of developing a subsequent breast cancer for women with endometrial cancer was 1.25-2.0 times the normal risk. Three of the 5 multiple primary soft tissue sarcomas developed as sequelae to previous breast cancers. It appeared that the positive association of multiple primary carcinomas of the breast, ovary and endometrium represented demographic and etiologic factors common to these conditions.

- 1622 THE EPIDEMIOLOGY OF MALIGNANT TUMORS. (It.) Susanna, L. (Inst. Hyg., U. Pavia, Italy), A. Marinoni and E. Lanzola. *Ig Sanit Publ* 26(7-8):269-282, 1970.

An increase in death rate from cancer from 1.1% to 1.9% within the last 10 yr was observed in the province of Bergamo. The cancer incidence was 2.3% in males and 1.6% in females. The populations living in industrial areas had a higher cancer incidence than those from rural areas; this difference appeared to be most visible among populations above 50 yr-of-age (4.6% vs. 3.5%, resp.). The urinary tract, the genital organs, the lung, intestine and liver appeared to be among the organs most susceptible to neoplastic development. No significant differences related to the altitude of the populated areas (excluding the industrial areas) were seen in tumor incidence; however, there seemed to be a decrease in cancer mortality with decreasing altitude.

- 1623 INCIDENCE OF BRONCHOGENIC CARCINOMA IN NEGROES: STATISTICAL ANALYSIS OF 94 CASES. (E.) Rickard, V. D. (Dept. Path., Howard U., Washington, D. C.) and C. C. Sampson. *J Nat Med Ass* 63(1):10-12, 1971.

The pathology of bronchogenic carcinoma in the American Negro was investigated in a study of 94 patients. Seventy-five were male, and 19 were female; 37 were aged between 51-60 yr, 33 were aged between 61-70 yr, and 15 were aged between 41-50 yr. Squamous cell carcinoma was the most common diagnosis (45.7% of cases), followed by undifferentiated carcinoma (40.4%). More females had undifferentiated carcinoma than any other type of lesion, while squamous cell carcinoma was the predominant pathologic type among males. A relationship was found between development of bronchogenic carcinoma and cigarette smoking. The incidence of carcinoma was 40% greater in smokers of more than 1 pack/day than in nonsmokers. Of 63 smoking pa-

patients, 27 developed squamous carcinoma, 23 developed undifferentiated carcinoma, and 7 developed adenocarcinoma.

1624 EPIDEMIOLOGICAL STUDY OF PRECANCEROUS LESIONS OF THE ORAL CAVITY: A PRELIMINARY REPORT. (E.) Mahi, P. N. (Indian Counc. Med. Res., New Delhi), V. P. Mital, B. Lahiri, U. K. Luthra, R. K. Seth and G. D. Arora. *Indian J Med Res* 58(10):1361-1391, 1970.

A survey of 534 cases of oral and oropharyngeal carcinoma, representing 7% of the screened population of Mainpuri district (India) revealed that leukoplakia was the predominant form of oral-oropharyngeal cancer in this population. Male cases were found to outnumber female cases by more than 3 to 1. The rate of oral-oropharyngeal carcinoma increased with increasing age, 44 cases occurring in the 35-39 yr group and 70 cases occurring in the 50-54 yr group. Hindus had a higher incidence of leukoplakia and submucous fibrosis than Muslims, and cultivators, laborers and "skilled workers" had significantly higher rates of oral-oropharyngeal cancer generally than did other occupational groups. Median income groups and groups having relatively high levels of education showed increased frequencies, persons with a "primary" education having prevalence rates of 163.3 and illiterate persons having rates of 46.9. Tobacco chewing was highly correlated with incidence of leukoplakia; the risk for this condition was 62 times higher in daily tobacco-chewers than in non-chewers. Those acquiring the tobacco chewing habit early in life were at greater risk of developing precancerous lesions of the oral cavity than those who began to chew tobacco at a later age. Increased risk of developing oral-oropharyngeal cancer was higher in those who chewed tobacco for 200 min/day or longer than for those who chewed tobacco for less than 200 min/day. Higher risks for oral-oropharyngeal precancerous lesions were associated with the use of chewing tobacco compounded of tobacco, betel, clove and lime than with the use of pure chewing tobacco. Tobacco smoking also predisposed to oral-oropharyngeal cancer, but to a lesser extent than did tobacco chewing; smoking potentiated the carcinogenic effects of chewing in those who indulged in both habits.

1625 LEVELS OF SERUM CHOLESTEROL AMONG OFFSPRING OF PARENTS WHO DIED OF CANCER: A COMPARISON WITH CORONARY HEART DISEASE. (E.) Deutscher, S. (Dept. Prevent. Med., Dalhousie U., Halifax, Nova Scotia, Canada). *J Nat Cancer Inst* 46(2):217-224, 1971.

In an epidemiological study of the population of Teumseh, Michigan, the maternal mortality from cancer was shown to be high in cases where the levels of serum cholesterol in the offspring were low; conversely, maternal mortality was low where serum cholesterol levels in the offspring were high. The correlation was more striking among deceased mothers of younger offspring. Thus, for sons aged 30-49 yr with low serum cholesterol, 8.3% of the mothers had died of cancer, while for sons in the same age group with high serum cholesterol, 4% of the mothers had died of

cancer. For sons aged 50 yr or more with low and high serum cholesterol, mothers dying of cancer were 13% and 11%, resp. The high maternal cancer mortality associated with low serum cholesterol levels represented a reversal of the trend noted for maternal deaths from coronary heart disease, in which higher deaths were associated with high serum cholesterol among offspring. The results obtained for paternal cancer mortality contrasted with those obtained for maternal cancer deaths; a greater percentage of fathers died from cancer at an earlier age when their sons and daughters had relatively high serum cholesterol levels than fathers of offspring with low cholesterol levels. It was speculated that persons with low serum cholesterol contents possess other inheritable characteristics which they transmit to their offspring, and which are related to cancer development among younger women.

1626 PERIPHERAL MEASURABLE BRONCHOGENIC CARCINOMA: GROWTH RATE AND PERIOD OF RISK AFTER THERAPY. (E.) Weiss, W. (Hahnemann Med. Coll., Philadelphia, Pa.). *Amer Rev Resp Dis* 103(2):198-208, 1971.

The relationship between the growth rate of bronchogenic carcinomas and survival was investigated in 41 male lung cancer patients with solid tumors whose diameter could be measured on roentgen films. At the time of detection of the tumors 46% of the tumors measured 2.0-2.9 cm in diameter, and 11 measured 4.0-4.9 cm. Forty percent of the tumors were squamous cell carcinomas, 19% were undifferentiated carcinomas, 33% were adenocarcinomas, and 8% were mixed tumors. All but 2 of the squamous cell carcinomas and all but 1 of the undifferentiated carcinomas doubled in volume in less than 6 months, while 59% of the adenocarcinomas had doubling times longer than 6 months. There was no apparent correlation between survival of patients treated with radiation and doubling time of the tumors. When survival of patients treated by resection of rapidly growing tumors was plotted against doubling time from the time that the tumors were 2 cm in diameter, 2 populations could be separated. In one group 16 men died within a period of 52 months with rapidly growing tumors; in the other group, 7 patients had markedly longer survivals, some surviving at the termination of the study (10 yr), and 1 dying 113 months after his tumor had attained a diameter of 2 cm. For men with rapidly-growing cancers, there seemed to be a period of risk of about 50 months from the time the tumor reached 2 cm in diameter. For men with slowly-growing cancers a period of risk could not be satisfactorily extrapolated.

1627 PROLIFERATION KINETICS OF SARCOMA-180. (E.) Nishioka, B. (Kyoto Prefect. U. Sch. Med., Japan). *Gann* 61(6):563-568, 1970.

Cellular proliferation kinetics of sarcoma-180 in C3H mice has been studied both peripherally and centrally through ^3H -thymidine labeling. Six of 7 transplanted tumors grew continuously showing exponential gain by the 7th day after transplantation with the growth curve declining gradually and reaching a pla-

teau by the 12th day. Changes in the percentages of labeled mitotic figures for the tumors at 5, 8 and 12 days revealed essentially similar curves. The duration of the mitotic cycle varied from 13.5-14.5 hr, while the period of DNA synthesis ranged from 7.0 to 8.5 hr, the postsynthetic phase from 3.0 to 4.5 hr, and the postmitotic phase from 1.7 to 3.2 hr for all groups. Labeling indices varied from 43.8% for the 5-day-old tumor to 29.1% for the central portion of the 12-day-old tumor, showing a tendency toward gradual decline with development of the tumor. Mitotic indices ranged from 1.5% to 1.0% in the 5-day-old and 12-day-old tumor, resp., while the peripheral growth fraction was approximately 72.1% in all tumors. The present results appear to favor the concept that the slowing down of the growth rate may be explained on the basis of reduction of the growth fraction; however, increase in cell death may also be a contributing factor.

1628 CLINICAL STUDY AND TOPOGRAPHICAL DISTRIBUTION OF MALIGNANT TUMORS OF THE FACE AND NECK IN TUNISIA: SEVEN HUNDRED CASES FROM THE NATIONAL CANCER INSTITUTE OF TUNIS. (Fr.) Brugere, J. (Inst. Gustave Roussy, Villejuif, France) and A. Zaouche. *Bull Cancer* 57(3):345-354, 1970.

1635 ELECTRON PROBE ANALYSIS FOR IODINE IN HUMAN THYROID AND PARATHYROID GLANDS, NORMAL AND NEOPLASTIC. (E.) Banfield, W. G. (Nat'l. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), P. M. Grimley, W. G. Hammond, C. M. Taylor, B. DeFlorio and A. J. Tousimis. *J Nat Cancer Inst* 46(2):269-273, 1971.

Tissues from normal thyroid, normal parathyroid, thyroid adenomas, parathyroid adenomas, medullary carcinomas of the thyroid, and thyroid carcinomas were examined for iodine content using the electron probe X-ray microanalyzer. All normal thyroid glands and thyroid adenomas contained iodine; however, with 1 exception, none of the parathyroid glands, parathyroid adenomas, medullary carcinomas of the thyroid, or undifferentiated or follicular thyroid carcinomas contained iodine. In normal thyroid and thyroid adenomas, iodine was found in amounts exceeding 0.004% (the minimal limit of detectability) in the follicular colloid. Cells lining the follicles of thyroid and thyroid adenomas did not contain iodine. Iodine, where present, remained detectable in sections stained with hematoxylin and eosin.

1636 SUBRIBOSOMAL PARTICLES SEPARATED FROM LIVER AND HEPATOMA HOMOGENATES WITH A ZONAL ROTOR. (E.) Mullock, B. M. (Wolfson Bioanal. Ctr., W. Surrey, Guildford), R. H. Hinton, M. Dobrota, D. Broomberg and E. Reid. *Europ J Biochem* 18(4):485-495, 1971.

Subribosomal particles which had been labeled *in vivo* were isolated in quantity from rat liver and hepatoma homogenates by centrifugation in a zonal rotor, and the RNA content was analyzed by means of electrophoresis and base-ratio analysis. Subribosomal particles containing rapidly labeled RNA were separated at 47,000 rpm for 165 min from liver and transplanted hepatomas to give 3 or 4 fractions. The 40S region was free from contamination by ribonucleoprotein from other regions but showed heterogeneity in itself, the 60S and 80S regions were contaminated with material from neighboring regions and with ferritin. The 40S region contained rapidly labeled RNA which differed from that expected for 28S RNA, indicating the presence of non-ribosomal RNA. The hepatoma 40S region gave no evidence of heterogeneity, and the 60S region contained large amounts of ribonucleoprotein in the form of large ribosomal subunits. The differences between hepatoma and liver in the proportion and characteristics of the subribosomal particles may reflect differences between normal and tumor tissues in the control of protein synthesis which is governed by the supply of different components of polysomes.

1637 TARTRATE-RESISTANT ACID PHOSPHATASE ISOENZYME IN THE RETICULUM CELLS OF LEUKEMIC RETICULOENDOTHELIOSIS. (E.) Yam, L. T. (New England Med. Ctr. Hosp., Boston, Mass.), C. Y. Li and K. W. Lam. *New Eng J Med* 284(7):357-360, 1971.

Leukocyte acid phosphatase isoenzymes were studied in 6 normal subjects, 5 patients with chronic lym-

phocytic leukemia, 2 with generalized lymphosarcoma with neoplastic cells in the peripheral blood, and 3 with leukemic reticuloendotheliosis. Leukocyte suspensions were prepared from blood, centrifuged and subjected to electrophoresis. Normal subjects and patients with lymphosarcoma and chronic lymphocytic leukemia showed 4 isoenzyme bands, with isoenzyme 1 stronger than 2, 3 or 4 in normals, and isoenzyme 3 predominating in leukemia patients. Tartaric acid inhibited the activity of all 4 isoenzymes in these subjects. Five isoenzymes were seen in the leukemia reticuloendotheliosis patients, and the 5th was predominant. Fluoride and molybdate inhibited all 5 isoenzymes in these patients; tartaric acid inhibited isoenzymes 1-4 but not isoenzyme 5. In leukemic reticuloendotheliosis, the acid phosphatase in monocytes, eosinophils, neutrophils and lymphocytes was similar to the acid phosphatase in these cells in normal subjects. In all subjects, reticulum cells showed acid phosphatase activity; this activity was resistant to tartaric acid. In leukemic reticuloendotheliosis patients, isoenzyme number 5 was located almost exclusively in the reticulum cells; this enzyme may be useful as a marker enzyme for leukemic reticuloendotheliosis.

1638 MEASUREMENT OF THYROCALCITONIN-LIKE ACTIVITY IN URINE OF PATIENTS WITH MEDULLARY CARCINOMA. (E.) Voelkel, E. F. (Harvard Sch. Dent. Med., Boston, Mass.) and A. H. Tashjian, Jr. *J Clin Endocr* 32(1):102-109, 1971.

A method for concentrating hypocalcemic activity from the urine of 10 patients with medullary carcinoma of the thyroid gland by means of adsorption with powdered silica is described. The final concentrated eluate contained detectable amounts of hypocalcemic activity when the original urine was from patients with medullary carcinoma, but the final eluate from normal subjects had no detectable activity even when concentrated 100 times. The concentrated material gave log dose-response lines in the bioassay which were linear and parallel to the Medical Research Council Research Standards with values of 0.2 to 72 MRC mU/ml urine compared to the normal excretion of less than 0.2 MRC mU/ml. Acute rises in serum thyrocalcitonin followed infusions of both calcium and glucagon with a rise in urinary excretion of hypocalcemic activity in subsequent collection periods for patients with medullary carcinoma. The knowledge that a positive relationship exists between plasma and urine thyrocalcitonin levels should make it easier to perform metabolic clearance studies and perhaps utilize urine bioassays as diagnostic tools.

1639 EFFECT OF OLEIC AND LINOLEIC ACIDS ON THE MONODESATURATION *IN VITRO* OF STEARIC ACID BY THE LIVERS OF PATIENTS SUFFERING FROM MALIGNANT NEOPLASTIC DISEASES. (E.) Nakazawa, I. (Tohoku U. Sch. Med., Sendai, Japan), S. Yamagata and M. Uchiyama. *Tohoku J Exp Med* 102(3):283-288, 1970.

Abnormal metabolic regulation in the mono-desaturation of stearic acid in human livers of patients suffering from malignant neoplastic diseases was examined *in vitro* using biopsy homogenates. Mono-

desaturation of labeled stearic acid to oleic acid was recognized in 5 cases of non-malignant disease and in 6 cases of malignant neoplastic disease with values of mono-desaturation percentages ranging from 4.1 to 20.9 in the non-malignant cases and between 3.8 and 10.8 in the malignant neoplastic cases on the basis of desaturating activity per 50 mg protein of the enzyme preparation. Inhibitory effects of oleic acid and linoleic acid in the conversion of labeled stearic acid was observed in all non-malignant liver homogenates, but in malignant cases the inhibition was observed in only 1 of 3 cases with respect to oleic acid and in only 2 of 6 cases with respect to linoleic acid. Where inhibitory effects of both acids were examined, the inhibition percentage values with oleic acid were larger than with linoleic acid in non-malignant as well as malignant neoplastic cases. Abolition of the inhibitory effect should be examined with respect to other metabolic reactions, such as esterification of free fatty acids and phospholipid synthesis to clarify present findings.

1640 FLUORESCENCE CYTOPHOTOMETRIC FEULGEN-DNA MEASUREMENTS OF BENIGN AND MALIGNANT HUMAN TUMORS. (E.) Böhm, N. (Dept. Path. U. Freiburg, Germany), E. Sprenger and W. Sandritter. *Beitr Path* 142(2):210-220, 1971.

Benign and malignant (primary and secondary) human tumors were examined for DNA distribution patterns utilizing fluorescence Feulgen cytophotometry. Histograms of an adenoma of the prostate, cystadenoma of the ovary, fibromyoma of the uterus and spindle cell leiomyosarcoma of the uterus revealed DNA content to be diploid in character, whereas those obtained from malignant tumors revealed hyperdiploid, triploid and tetraploid, hypertetraploid, hexaploid and octoploid DNA ranges (adenocarcinoma of the endometrium, squamous carcinoma of the bronchus and clear cell renal carcinoma). Metastatic lesions revealed DNA content which ranged from hypertetraploid to hyperoctoploid peaks mainly with an anaplastic choriocarcinoma of the uterus showing DNA values up to 20-ploid. In general doubling peaks were much less prominent in benign lesions than in malignant conditions.

1641 RNA DIRECTED DNA SYNTHESIS: IDENTIFICATION IN L5178Y MOUSE LEUKEMIC CELLS AND DISTRIBUTION OF THE POLYMERASE IN A SYNCHRONIZED L5178Y CELL POPULATION. (E.) Bosmann, H. B. (U. Rochester Sch. Med. Dent., New York). *FEBS Letters* 13(2):121-123, 1971.

Characteristics of an RNA dependent DNA polymerase from L5178Y mouse leukemic cells and its activity during normal DNA synthesis were studied utilizing thymidine cell labeling. The enzyme showed lack of degradation by RNase and degradation by DNase, trichloroacetic acid insolubility, and alkali resistance and was dependent on Mg^{2+} and dATP, dCTP and dGTP. Yeast RNA was relatively ineffective as a template. The enzyme was active throughout the cell cycle with highest activity occurring at 9.5 hr post-mitosis in the early M period. The results indicate

that RNA dependent DNA polymerase is active throughout the cell cycle and apparently is present for formation transfer from RNA viruses or for gene amplification.

1642 PLASMA AND TUMOR CONTENT OF STEROIDS AND STEROID SULFATES IN TWO CASES OF ADRENOCORTICAL VIRILIZING CARCINOMA. (E.) Saez, J. M. (Hosp. Debrousse, Lyon, France), B. Loras, A. M. Morera and J. Bertrand. *J Steroid Biochem* 1(4):367, 1970.

The isolation and measurement of several C-19 and C-21 steroids in both unconjugated and sulfate form in 2 cases of adrenal virilizing tumors in children are reported including plasma concentrations in peripheral and adrenal veins by means of radioactive labeling and gas chromatography. Tumor tissue of case II quantitated by means of gas-liquid chromatography gave the following results: dehydroepiandrosterone 2.96 $\mu\text{g/g}$ tissue; sulfated derivative 7.1 $\mu\text{g/g}$ tissue; pregnenolone 0.95 $\mu\text{g/g}$ tissue; pregnenolone sulfate 3.12 $\mu\text{g/g}$ tissue. With a double isotope dilution technique, readings were similar. In the aldosterone fraction of both tumors, in the cortisone fraction of case I, and in the deoxycorticosterone fraction of case II, a constant $^3\text{H}/^{14}\text{C}$ ratio could not be obtained due possibly to low tumor content. Tumor tissue from case I revealed the presence of unconjugated androstenediol, corticosterone, 11-deoxycortisol and cortisol in addition to androstenediol sulfate, while tissue from case II was positive for androstenediol, corticosterone, 11-deoxycortisol and sulfated androstenediol. Peripheral plasma concentrations were generally elevated in both instances with increases in 5-en- 3β -ol steroids in case I and 11 β -hydroxyandrostenedione in case II. In patient II, for all steroids measured with the exception of unconjugated testosterone, the levels in adrenal vein plasma were 2-10 times higher than in peripheral plasma, indicating secretion of the steroids by the tumor. In both cases, significant quantities of testosterone sulfate were isolated, although the tumors did not secrete unconjugated testosterone.

1643 ADENOSINE METABOLISM IN PLASMA AND PLATELETS: IV. ELEVATED PLASMATIC ADENOSINE DEAMINASE ACTIVITY, IMPAIRED PLATELET ^{14}C -ADENOSINE INCORPORATION AND HEMOSTATIC DYSFUNCTION IN CHRONIC MYELOID LEUKEMIA. (E.) Pinkhas, J. (Tel-Aviv U. Med. Sch., Israel), J. J. Chivot, H. Michel and J. Caen. *Rev Eur Etud Clin Biol* 15(10):1108-1113, 1970.

Adenosine deaminase activity (ADA) in plasma from 12 patients with chronic myeloid leukemia was determined by ^{14}C -inosine formation from ^{14}C -adenosine in plasma. ADA was elevated in 11 of 13 examined patients; in 1 patient, ^{14}C -inosine activity was at 46.1 nM/min, as compared to 19.4 nM/min for a normal control; ADA levels were generally elevated by a factor of 2-3 in leukemia patients. The effect of leukemic plasma on platelet ^{14}C -adenosine incorporation was observed in 5 patients; ^{14}C -adenosine incorporation in platelets incubated with leukemic plasma was generally reduced by a factor of 1.5-2. No relation

ship was found between elevated ADA and peripheral WBC and RBC counts, differential counts, and hemoglobin determination. ADP consumption was increased in 8 and normal in 3 patients with leukemia. Most patients also had decreased serum aggregating activity, decreased platelet acid phosphatase availability and normal platelet factor 4. Platelet aggregation studies performed with leukemic platelets in their own plasma showed that the aggregation induced by collagen, ADP and epinephrine were generally abnormal. Primary hemostasis in chronic myeloid leukemia seems to depend on an interaction of plasmatic factors such as ADP and adenosine degradation and intracellular factors such as platelet adenosine incorporation and release of platelet nucleotides.

544 LYMOPROLIFERATIVE DISEASES OF FOWL: ALTERATION IN LACTATE DEHYDROGENASE ISOZYMES ASSOCIATED WITH LYMPHOBLASTIC LEUKEMIA (JM-V). (E.) Adams, M. L. (Dept. Anim. Dis., U. Connecticut, Storrs), A. J. Kenyon, N. D. Jones, F. Schmidt and S. N. Kim. *J Nat Cancer Inst* 61(1):43-48, 1971.

Elevated serum lactate dehydrogenase isozyme levels associated with JM-V (a highly lethal strain of neurotropic lymphoproliferative disease of domestic fowl) lymphoblastic leukemia were investigated in many-old sex-linked, Barred Rock-Rhode Island Red crossbred cockerels by photodensitometry. Serum levels of lactate dehydrogenase and isocitrate dehydrogenase increased abruptly between 4 and 5 days post-inoculation to 21,400-33,700 U and 9,520 U of lactate dehydrogenase and isocitrate dehydrogenase, resp., on the 6th post-inoculation day compared to controls with 1,240-1,630 U for lactate dehydrogenase and 1,110 U for isocitrate dehydrogenase, while serum glutamate-oxalacetate transferase levels ranged from 380-810 U compared to 305-390 U in controls. At 6 days post-inoculation, spleen weights ranged from 110-346 mg whereas spleen controls ranged from 2-41 mg; liver weights ranged from 2.2-4.2 g in infected fowl as opposed to a range of 1.3-3.1 g in controls; bursa weights remained unchanged. Peripheral smears revealed numerous lymphocytes and large lymphoblasts in various stages of mitosis during the period of rapid increase in lactate dehydrogenase and isocitrate dehydrogenase. Isozyme distribution during increased lactate dehydrogenase is similar to that in lymphoid tissue as represented by the bursa, suggesting the lymphoblast as the main source of this alteration in enzyme levels.

545 LYSOSOMAL ENZYME ACTIVITY IN LIVER TISSUE, KIDNEY TISSUE, AND TUMOR TISSUE FROM PATIENTS WITH RENAL CARCINOMA. (E.) Schersten, T. Wahlgrenska Hosp., Göteborg, Sweden), L. Wahlgren and B. Jilderos. *Cancer* 27(2):278-283, 1971.

Lysosomal enzyme activity was investigated in liver tissue, kidney tissue, and kidney tumor tissue in patients with renal carcinoma. Total activities of acid phosphatase, aryl sulfatase, cathepsin and glucuronidase in livers from renal carcinoma patients were increased compared to these activities

in patients without renal carcinoma. In controls, liver acid phosphatase activity totaled 14.75 μ moles P_i /mg protein/min and cathepsin totaled 4.70 μ moles tyrosine split/mg/min; in renal carcinoma patients, values for liver acid phosphatase and cathepsin were, resp., 18.63 and 5.96 μ moles/mg/min. Cathepsin activity was found to be higher in patients with comparatively large renal tumors. The activities of lysosomal enzymes in kidney tissues from renal carcinoma patients were similar to those activities in livers of controls; however, aryl sulfate activity was higher in renal carcinoma patients' kidney tissue than in control livers. Enzyme activities in renal carcinoma tissue were lower than in liver and in non-malignant kidney tissue; acid phosphatase in the peripheral part of renal tumors was 5.47 μ moles P_i /mg/min. Ratios between total and free enzyme activity were higher in the areas than in the central parts of the tumors, the differences between central and peripheral free/total ratios being 1.2 for acid phosphatase and 1.4 for aryl sulfatase and cathepsin. High activities of lysosomal enzymes tended to be found in tumors of patients having high total enzyme activities in liver tissue. Lysosomal enzymes may be released from tumor tissue to be taken up by other tissues where they continue to be active.

1646 VARIATION OF DIHYDROFOLATE REDUCTASE ACTIVITY DURING *IN VITRO* AND *IN VIVO* GROWTH OF SUBLINES OF L1210 LYMPHOMA. (E.) Hillcoat, B. L. (Dept. Biochem., McMaster U., Hamilton, Ontario, Canada). *J Nat Cancer Inst* 46(1):75-80, 1971.

The increased activity of the enzyme dihydrofolate reductase (DHFR) in methylcholanthrene-induced lymphomas was studied by establishing three cloned strains of L1210 lymphoma cells in the DBA strain of mouse. The doubling time of LS2, LM1, and LM4 clonal lines was initially 16 hr *in vitro* and increased to 19 hr 3 months later, growing logarithmically for 2-2½ days. *In vivo* ascites cells grew logarithmically after a lag of 1 day with a doubling time of 24 hr for 2 days followed by a slower increase. Clones LS2 and LM1 caused death of all treated animals by day 12 while animals carrying LM4 cells survived and showed a decrease in cell count after day 10. LS2 cells contained 40 chromosomes including a subtelocentric marker similar to that found in the parent line; LM4 and LM1 were hypoploid with 36 chromosomes each, with the former possessing the subtelocentric marker. Fifty percent growth inhibition of LS2, LM1, and LM4 cells occurred at 2.5×10^{-9} , 1×10^{-8} , 3.5×10^{-8} M methotrexate, resp. Maximum DHFR activities of the 3 cell lines were similar *in vitro* and *in vivo* with the LM4 cells containing 5-6 times the amount of enzyme of the LS2 cells and 9 times that of LM1 cells. The specific activity of DHFR of LM4 cells *in vivo* was 10 times that of LS2 and LM1, but only five times *in vitro*. Cell count, protein concentration and enzyme activity were closely related; however, specific activity tended to change less than enzyme activity per 10^7 cells *in vitro*, indicating a rate of loss of DHFR comparable to the bulk of cellular protein. The significant differences of

the three clonal lines reflect the heterogeneity of the parent L1210 cells.

- 1647 ISOLATION OF A TUMOR FACTOR RESPONSIBLE FOR ANGIOGENESIS. (E.) Folkman, J. (Child. Hosp. Med. Ctr., Boston, Mass.), E. Merler, C. Abernathy, and G. Williams. *J Exp Med* 133(2):275-288, 1971.

A tumor angiogenesis factor (TAF) mitogenic to capillary endothelial cells was isolated from various different tumor tissues and shown in experiments with rats to promote vascular proliferation *in vivo*. Isolation of the TAF was achieved by high-speed centrifugation of tumor tissue homogenates and fractionation in column chromatography. Walker 256 ascites tumors, B-16 mouse melanomas, human neuroblastomas, Wilms' tumors and hepatoblastomas all demonstrated TAF; human neuroblastomas showed the greatest ability to promote vascular proliferation. TAF was found to be composed of RNA and proteins, and it was suggested that blockage of the TAF factor may arrest solid tumors in the early stages of growth.

- 1648 STIMULATION OF LIVER DNA SYNTHESIS BY A FACTOR FROM ASCITES TUMOR 6C3HED. (E.) Yarbro, J. W. (U. Kentucky Med. Ctr., Lexington). *Int J Cancer* 7(1):176-181, 1971.

Partial isolation and characterization of a factor from 6C3HED mouse ascites tumor capable of stimulating liver DNA synthesis in non-tumor bearing animals is reported. Incorporation of label into the liver DNA of young C3H mice was a function of time in which a plateau was reached within 2 hr for labeled orthophosphate and within 30 min for labeled thymidine. After inoculation of the ascites tumor, a gradual increase in the rate of label incorporation was seen compared to controls. Maximum stimulation of DNA synthesis was seen at 100 hr after injection of 0.005 ml ascites fluid. DNase and RNase did not abolish liver-stimulating activity but pronase markedly diminished this activity. The factor responsible for the liver-stimulating activity requires further purification and characterization.

- 1649 COLLAGENOLYTIC ACTIVITY IN THE SIMPLE SOLID CARCINOMA OF THE BREAST, RELATED TO DNA CONTENT. (Ger.) Keiditsch, E. (St. Hosp. Munich, Germany) and L. Strauch. *Verhandl Deutsch Ges Path* 54:438-442, 1970.

The increase in collagenase activity in the area of a solid mammary carcinoma was investigated to discover whether the increase was related to the increased number of tumor cells or whether the carcinoma cells themselves generated more collagenase. The tissues of the center of the carcinoma, the periphery, and the carcinoma free zone were examined for collagenase activity, DNA content and nitrogen content. The distribution of enzyme activity showed the enzyme to be increased in the periphery and decreased in the central core of the carcinoma, with lowest activity in the healthy tissue. The increase in collagenase activity was related to the DNA content,

indicating a higher production of enzyme by the tumor cells in this area. The increased collagenase activity in the periphery of the carcinoma appeared to be the result of an increase in the formation or deposition of the enzyme in the cancer cells, perhaps as an invasive factor in the growth of mammary carcinoma.

- 1650 STUDIES ON THE PEROXIDASE OF EXPERIMENTAL CHLOROMA. (Jap.) Tsuchimochi, T. (Showa U. Sch. Med., Tokyo, Japan). *Acta Haemat Jap* 33(4):388-401, 1970.

An experimental chloroma began to grow noticeably 1 wk after transplantation in rats and showed a high level of peroxidase activity at that time. Peroxidase activity was most conspicuous in the mitochondrial and lysosomal fractions of chloroma cells. Isolated peroxidase was thought to be bound with porphyrin and nucleic acid from its absorption spectrum. The bound nucleic acid was RNA, was readily isolated from the peroxidase, was similar to sRNA, and had a sedimentation coefficient of 5S on column chromatographic analysis. The porphyrin bound to peroxidase was protoporphyrin and had no influence on the peroxidase activity itself. The green pigmentation consisted mainly of peroxidase which had the characteristics of myeloperoxidase. It was thought that the porphyrin might have been bound to the peroxidase protein at the site of a vinyl bond.

- 1651 STUDY ON THE PROPOSED ROLE OF PHOSPHOLIPIDS IN TUMOR CELL MEMBRANE. (E.) Selkirk, J. K. (McArdle Lab. Cancer Res., U. Wisconsin, Madison). J. C. Elwood and H. P. Morris. *Cancer Res* 31(1):27-31, 1971.

The phospholipids in plasma membranes from slowly and rapidly growing solid hepatomas and from normal liver cells were compared; the structural alterations, degree of membrane fatty acid unsaturation, and amount of calcium and magnesium in the membranes were determined. The 2 hepatomas studied were the Morris 3924A tumor, an anaplastic, rapidly growing neoplasm, and the Reuber H-35 hepatoma, which has a relatively slow transplantation time. The Reuber tumor and normal liver cells had the same percentages of the individual plasma membrane phospholipids. The Morris tumor plasma membrane, however, contained plasmalogen (diphosphatidyl) glycerol amounting to 7.2% of total phosphorus, while the Reuber tumor and liver cells had no choline; the Morris tumor cell membrane 21.2% of total phosphorus was found in sphingomyelin, while percentage of sphingomyelin phosphorus for Reuber tumor and normal cell membranes were 8.3 and 9.1%, resp. The Morris tumor cell membrane contained 53% unsaturated lipid fatty acids, while percentages of unsaturated fatty acids from liver cells and Reuber tumors were 42 and 35%, resp. Both tumors showed increased membrane-bound calcium compared to liver cells, with Morris tumor membrane containing more calcium (88 µg/g dry wt) than the Reuber tumor membrane (233 µg/g). Liver cell membranes contained more magnesium

(89.5 $\mu\text{g/g}$) than either the Morris (33.6 $\mu\text{g/g}$) or the Reuber (69.6 $\mu\text{g.g}$) tumor cell membranes.

1652 COMPARISON OF THE MITOCHONDRIAL MEMBRANE PROTEINS IN RAT LIVER AND HEPATOMAS. (E.)

Chang, L. O. (U. Virginia Sch. Med., Charlottesville), C. A. Schnaitman and H. P. Morris. *Cancer Res* 31(2): 108-113, 1971.

Mitochondrial membrane proteins isolated from the liver mitochondria of normal rats and rats bearing hepatomas showed similar major protein bands on polyacrylamide gel electrophoresis. Mitochondrial membrane proteins were also isolated from well-differentiated, poorly differentiated, and undifferentiated hepatomas (H-35, 9098, H35-tc1, H35-tc2 and 3924-A). Gel patterns from tumor mitochondrial membranes were significantly different from those of livers from normal rats and from tumor-bearing rats. One major protein band observed in the membranes from normal liver was lacking or greatly reduced in all of the hepatoma membrane samples. Membranes isolated from a well-differentiated hepatoma (H-35) had an additional major band which was present in lesser amounts in other hepatoma membranes and which was absent or exiguous in the normal liver membranes.

1653 THE HORMONE-SYNTHESIZING TROPHOBLASTIC CELL IN VITRO: A MODEL FOR CANCER RESEARCH AND PLACENTAL HORMONE SYNTHESIS. (E.)

Pattillo, R. A. (Med. Coll. Wisconsin, Milwaukee), G. O. Gey, E. Delfs, W. Y. Huang, L. Hause, J. Garancis, M. Knoth, J. Amatruda, J. Bertino, H. G. Friesen and R. F. Mattingly. *Ann NY Acad Sci* 172(10):288-298, 1971.

A human choriocarcinoma was established as a cell line *in vitro* by serial transplantation in hamster cheek pouches, and the properties of the trophoblastic cells of the tumor were examined. Cells contained many desmosomes, active Golgi apparatus, and normal mitochondria. Human chorionic gonadotropin was produced by trophoblasts of the carcinoma in amounts similar to those produced by normal uterine cells; 1,000-5,000 IU of gonadotropin from the trophoblast cultures failed to stimulate an ovarian or uterine response, but 1 IU of follicle-stimulating hormone added to the gonadotropin produced hyperstimulation of ovarian activity and uterine hypertrophy. The trophoblast cell line produced small amounts of human placental lactogen, which correlated with the low levels of this hormone produced by patients with choriocarcinoma. Analysis of steroid biosynthesis in the tumor cells demonstrated the presence of the placental enzyme 3- β -ol dehydrogenase, in addition to progesterone and androstene. Methotrexate inhibited trophoblast growth; incubation of cells with a 10^{-5} M concentration of methotrexate inhibited the uptake of ^3H -uridine by cells in DNA synthesis by 100%; a concentration of 10^{-9} M of methotrexate produced no inhibition of label incorporation. The trophoblast cell line's karyotype remained stable through 150 passages, the modal number remaining 78-86. Malignant choriocarcinoma cells were found to have a transmembrane electrical potential of 35-50 mv, the lower value at pH 7 and the higher value at pH 8. The role of the sialomucin cell coat in producing the charged surfaces remains unclear.

1654 FLUOROGENIC AMINES IN THE C-CELLS THYROID TUMOURS OF MAN. (E.)

Beskid, M. (Postgrad. Med. Sch., Warsaw, Poland) and R. Lorenc. *Acta Histochem* 38(1):74-81, 1970.

Biopsy specimens from 12 human adenomas and 2 hyalinic medullary carcinomas revealed autofluorescence in collagen fibers under fluorescence microscopy. Unfixed sections treated with formaldehyde gas showed a yellowish fluorescence; the fluorescence was stronger in some cells than in others. Unfixed sections treated *in vitro* with dihydroxyphenylalanine showed no increase in yellow fluorescence. Substances isolated from the thyroid adenoma tissue produced a hypocalcemic effect when injected into rats. The observed yellow fluorescence was attributed to the presence of fluorogenic amines in the C-cell thyroid adenomas and carcinomas.

1655 LIPID METABOLISM IN CULTURED CELLS: GROWTH OF TUMOR CELLS DEFICIENT IN ESSENTIAL FATTY ACIDS. (E.)

Bailey, J. M. (George Washington U. Sch. Med., Washington, D.C.) and L. M. Dunbar. *Cancer Res* 31(2):91-97, 1971.

Growth of Ehrlich ascites carcinoma and sarcoma 180 were studied in normal CF₁ mice and CF₁ mice with pronounced essential fatty acid deficiency through periodic assay of the fatty acid composition in whole blood. Mice fed a fat-free diet grew more slowly than controls during the first 5 wk at which time they ceased growing, while control mice continued to gain weight for a further 4-6 wk. The sharpest decline in blood linoleic acid occurred during the first month in the deprived animals with a drop in blood lipids from 17.5% to less than 5% of the total fatty acid; at 6 months blood lipids decreased to 0.5% or less than 1/30 of the normal amount. Growth of tumors from cells harvested from Ehrlich ascites carcinoma showed a similar pattern in normal and deficient mice with a somewhat longer lag phase following inoculation. Similarly, cells harvested from a sarcoma 180 showed a somewhat longer lag period after inoculation into the deficient mice, but mean generation times measured over the entire growth curve were not significantly different. The total lipid content of the Ehrlich ascites tumor of the deficient mice (0.76 ± 0.13 mg lipid/ 10^7 cells) was not significantly different from that of normal cells (0.67 ± 0.12 mg/ 10^7 cells) despite decreases in linoleic acid and arachidonic acid due to simultaneous increases in palmitoleic acid, oleic acid, and eicosatrienoic acid. Increase in dividing time occurred in the initial stages of growth when both Ehrlich ascites and normal sarcoma 180 cells were transplanted into deficient mice, but growth rate returned to normal after the first 24-48 hr. This fact and the apparently normal transplantation characteristics of the deficient cells in both normal and deficient hosts suggests that the deficient environment did not represent any major metabolic stress.

1656 ECTOPIC PRODUCTION OF HUMAN CHORIONIC SOMATOMAMMOTROPIN BY NONTROPHOBLASTIC CANCERS. (E.)

Weintraub, B. D. (Natl. Inst. Arthri-

tis Metab. Dis., Natl. Inst. Hlth., Bethesda, Md.) and S. W. Rosen. *J Clin Endocr* 32(1):94-101, 1971.

Eleven of 128 patients with confirmed malignancies in sites other than trophoblastic or gonadal sites were found to have human chorionic somatomammotropin (HCS) in their plasma; case material in which HCS was detected included plasma from patients with lung carcinoma, hepatoma, lymphoma or leukemia, and pheochromocytoma. Unconcentrated plasma was examined in all cases; where HCS was not detected, the plasma was concentrated by affinity chromatography for re-examination. Of 80 subjects without malignancy, none had HCS in direct assay; none of 18 normal subjects whose sera were tested after concentration by affinity chromatography had HCS. Nine lung cancer patients showed HCS only in the concentrated serum examinations. Of 13 patients with untreated trophoblastic tumors, 8 had detectable HCS, and of 9 patients with treated trophoblastic tumors, one had detectable HCS. Untreated trophoblastic tumor patients had concentrations of HCS which were generally higher than those in patients with nontrophoblastic tumors. Unconcentrated serum of trophoblastic tumor patients showed HCS concentrations with maxima of 180 and 75 ng/ml, while maximum HCS concentrations in unconcentrated sera of patients with nontrophoblastic tumors were 14 and 9 ng/ml. Tumor extracts from 4 patients with undifferentiated large cell carcinomas of the lung and from 2 patients with choriocarcinoma contained HCS, whereas nonmalignant tissues from the same patients had no detectable HCS; in these patients, tumor and plasma HCS concentrations showed significant correlation. HCS production in these 4 patients was thought to be ectopic. The ectopic production of HCS suggests there is a link between ectopic hormones and ectopic embryonic proteins, and may indicate the presence of neoplasm.

1657 STIMULATION OF DNA SYNTHESIS *IN VITRO* IN MOUSE THYMIC CELLS BY BONE MARROW PREPARATION. (E.) Knyszynski, A. (Weizmann Inst. Sci., Rehovot, Israel) and M. Burger. *Blood* 37(2):231-239, 1971.

A factor present in mouse bone marrow preparations (BMP) which stimulates DNA-synthesis in mouse thymic cells *in vitro*, was compared with mouse kidney and spleen cell preparations. Incubation of thymic cells with the kidney cell preparation failed to stimulate DNA synthesis, and incubation with the spleen cell preparation reduced DNA synthesis from normal values by approximately 30%. BMP increased DNA synthesis in thymic cells by 41%, but human serum 19S alpha-2 globulin did not increase thymic DNA synthesis. BMP did not increase DNA synthesis in mouse mesenteric lymph node cells or in bone marrow cells. Protein synthesis in mouse thymic cells was stimulated only 24% by BMP; BMP stimulation of DNA occurred in the absence of protein synthesis (when blocked by puromycin) as well as in cells synthesizing protein. The bone marrow factor increased thymic DNA synthesis by 26% in mice with thymic leukemia as compared to a 46% increase in normals. The bone marrow factor stimulated thymic cell DNA synthesis only half as much in mice given 300 r of whole-body irradiation as in unirradiated mice. Puri-

fied bone marrow factor was resistant to heating at 100° even at low or high levels of acidity; however the factor was more sensitive to heat denaturation if it was in an impure state. Treatment with RNase, I pronase and carboxypeptidase did not affect the stimulatory activity of the bone marrow factor.

1658 STUDIES ON THE ORIGIN OF PROTEINS IN THE NUCLEOLI OF MOUSE ASCITES TUMOR CELLS: A TEST FOR PROTEIN TRANSFER TO THE NUCLEOLI. (E.) Kawashima, K. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), M. Izawa and S. Sato. *Biochim Biophys Acta* 232(1):192-206, 1971.

A transplanted mouse ascites tumor cell line was used in pulse-chase experiments of amino acids to investigate the transfer of protein molecules to the cell nucleolus from other cellular structures. Cessation of amino acid incorporation by the nucleolus after the pulse was achieved by administration of a 7500-fold excess of unlabeled amino acid and/or of 100-200 µg/ml cycloheximide to cells in culture. Radioactive-labeled proteins were found to increase by 70-100% in nucleoli during pulse-chase experiments; the increase in nucleolar proteins appeared to be the expense of small but significant decreases in radioactive protein in the cytoplasmic 25,000 x g supernatant fraction. In addition to the nucleoli, the 25,000 x g cytoplasmic sediment which may contain mitochondria and the extranucleolar nuclear fraction which consists of chromatin and nuclear scaffolds were found to receive proteins through transfer during the chase. The decline in radioactive-labeled proteins in the 25,000 x g cytoplasmic supernatant fraction during the chase appeared to be the result of a decrease in the 105,000 x g sediment fraction. A smaller increase was found in labeled proteins in the 105,000 x g supernatant fraction. The nucleolar 105,000 x g supernatant fraction and the nucleolar 105,000 x g sediment fraction appeared to be receiving sites for proteins synthesized elsewhere. Protein transfer to the nucleolus was diminished by lowering the temperature of the pulse-chase process; addition of 2,4-dinitrophenol to the medium diminished the amount of protein transferred to the nucleolus by 60%. Actinomycin D also suppressed the transfer of protein to the nucleolus. Apparently, incorporation of amino acids into the nucleoli in the living animal depends at least in part on the uptake of protein molecules produced on the outside of the nucleolus, probably in the cytoplasmic polyribosomes.

1659 ON THE REGULATION OF THE SYNTHESIS OF RIBOSOMAL PROTEINS IN L-CELLS. (E.) Craig, N. C. (Div. Biol. Sci., U. Maryland, Baltimore). *Molec Biol* 55(1):129-134, 1971.

The effect of low doses of actinomycin D on the synthesis of ribosomal proteins and ribosomal RNA was studied by isotopic labeling and electrophoresis in mouse L-cell fibroblasts. The cells were labeled with ¹⁴C-amino acids first and then with ³H-amino acids in the presence of actinomycin D (0.12 µg/20 ml). In the soluble protein fraction the ³H/¹⁴C ratio remained unchanged during the 11 hr of re-

covery even though the specific activity decreased by about 45% due to dilution with unlabeled newly synthesized protein. Relative ribosomal-soluble $^3\text{H}/^{14}\text{C}$ ratio from the cells after 11 hr of recovery was significantly less than 1.00, implying that the production of effective ribosomal protein has been specifically inhibited in comparison to synthesis of soluble protein. These results imply a co-ordinated regulation of the production of ribosomal RNA and ribosomal protein.

1660 ISOTOPE DILUTION DETERMINATIONS AND OTHER STUDIES OF CYTIDINE DIPHOSPHATE CHOLINE, CYTIDINE DIPHOSPHATE ETHANOLAMINE, DEOXYCYTIDINE DIPHOSPHATE CHOLINE, AND DEOXYCYTIDINE DIPHOSPHATE ETHANOLAMINE IN LIVER AND LIVER TUMORS. (E.) Schneider, W. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Nat Cancer Inst* 46(2):435-441, 1971.

The choline and ethanolamine content of normal and regenerating rat liver and of hepatomas in Sprague-Dawley rats was studied by means of isotope dilution determinations. Concentrations of deoxycytidine diphosphate-choline and deoxycytidine diphosphate-ethanolamine was much greater in the Novikoff hepatoma than in normal liver with decreases in choline and increases in ethanolamine 24 hr after partial hepatectomy. The concentration of cytidine diphosphate-choline was about the same in normal and Novikoff hepatomas and doubled 12 hr after hepatectomy in hepatoma 5123, while cytidine diphosphate-ethanolamine concentrations were greater in hepatoma 5123 and in regenerating liver at both 12 and 24 hr after partial hepatectomy compared to normal liver. Homogenates of the Novikoff hepatoma incubated with labeled deoxycytidine diphosphate ethanolamine showed significant incorporation into DNA; suppression of this activity resulted from the addition of P-ethanolamine cytidyl transferase compared to enhanced incorporation by cells treated with labeled deoxycytidine diphosphate. No evidence for the conversion of cytidine diphosphate-choline to deoxycytidine diphosphate-choline or for direct incorporation of deoxycytidine diphosphate-ethanolamine into the DNA of the Novikoff hepatoma was found; no satisfactory explanation can be given for the increased levels of deoxycytidine diphosphate-choline and ethanolamine in hepatomas and regenerating liver.

1661 HYBRID CELLS IN SOLID TUMORS. (E) Janzen, H. W. (Surg. Med. Res. Inst., U. Alberta, Edmonton, Canada), P. A. Millman and O. G. Thurston. *Cancer* 27(2):455-459, 1971.

In vitro hybridization between cells of murine lines Sarcoma-180 (Foley) and L-5178Y lymphoblast was studied in 131 C3H mice over a 21-day period through observation of growth characteristics and karyotype analyses. Chromosome analysis of 100 cells of Sarcoma-180 in isolated culture showed 92 low ploidy and 8 high ploidy cells with the chromosome numbers for the stemline cells ranging from 80-90, whereas 100 cells of L-5178Y consisted of 70 low and 30 high ploidy cells with the number for the low ploidy cells ranging from 38-43 and for the high ploidy from 76-86. Chromosome analysis of 200

apparently intact cells of mixed *in vitro* cultures showed 9 cells to be hybrids with a complete or near complete set of chromosomes from each parent line. *In vivo* tumor growth analysis revealed Sarcoma-180 (Foley) grew progressively as a solid tumor in the thigh muscle reaching an average diameter of 2.6 cm in 28 mice with no evidence of metastasis 21 days after inoculation; the L-5178Y tumor appeared as a palpable mass within 5 days after inoculation and reached a maximum average diameter of 0.9 cm in 25 mice on the 8th post-inoculation day after which it regressed completely with no evidence of metastasis on day 21; the mixed lymphoblast tumor reached a maximum average diameter of 1.2 cm in 32 animals on the 8th day followed by regression which remained as a small focus at the site of inoculation but produced no metastatic lesion. Chromosome analysis of both pure tumors showed no change in karyotype as a result of passage through the host mice, whereas hybrid cells appeared with the mixed tumor. The low frequency of hybrid cells in the mixed tumor makes it unlikely that the intermediate behavior of these tumors is determined by such cells.

1662 ELECTRON MICROSCOPIC STUDY OF BRONCHOGENIC SQUAMOUS EPITHELIAL CARCINOMA CELLS. (Ger.) Zimmer, S. (Cytodiag. Central Lab., Grimma, Germany) and M. Kühnert. *Z Erkrank Atmungsorg* 132(3):351-354, 1970.

Electron microscopic studies were conducted in histologically confirmed bronchogenic squamous epithelial carcinoma with the object of finding possible structural specificity. Some of the general changes in malignancy as seen by the electron microscope were: loss of ciliary differentiation, loss of polarity, a change from metaplasia to anaplasia, transformation to squamous epithelia, and coagulation necrosis. Nuclear changes were invagination, marginal condensation of the chromatin, and infiltration. Changes seen in the cytoplasm and its organelles were enlargement of intercellular vacuoles, broad desmosomes, peripheral condensation of fibrils, disturbances in the internal structure of the mitochondria, thickening of the endoplasmic reticulum, dilatation, cleft formation, cisterns, sequestration, and increased lysosomes.

1663 NUCLEAR POCKETS ASSOCIATED WITH THE NUCLEOLUS IN NORMAL AND NEOPLASTIC CELLS. (E.) Burns, E. R. (U. Arkansas Med. Ctr., Little Rock) B. L. Soloff, C. Hanna and D. F. Buxton. *Cancer Res* 31(2):159-165, 1971.

Nuclear pockets appearing as simple invaginations of the nuclear envelope filled with cytoplasm were found in cells prepared from Ehrlich ascites tumor, chick embryo lens, human amelanotic malignant melanoma of the ciliary process, and human corneal epithelium from Fuchs' dystrophy. Nuclear pockets, although seen in all cell preparations, were most common in malignant melanoma cells. Many of the pockets extended toward the nucleoli or were otherwise associated with them. Nuclei with multiple pockets or with branching pockets were rare. Nuclear pockets may

function to increase nuclear-cytoplasmic interaction by increasing their contact surface area.

- 1664 AMYLOID-LIKE DEPOSITS IN LUNG CANCER AND BRONCHIAL ADENOMA. (Ger.) Kozlowski, H. (Med. Acad. Gdansk, Poland), M. Hrabowska and R. Polonski. *Arch Geschwulstforsch* 36(4):370-384, 1970.

Morphological analysis of pulmonary carcinoma and bronchial adenoma tissues was performed with particular attention to amyloid-like deposits; the material for analysis comprised 129 cases of lung cancer and 21 cases of bronchial adenoma and was collected either from biopsies or autopsy specimens. Among the lung carcinomas, 4 cases of oat-cell carcinoma showed hyaline masses which were positive to Congo Red and appeared both in the primary lesion and in the metastases. The cellular structure of the tumors included solid uniform epithelial conglomerations. Diffuse stroma and few blood vessels were seen, and fibrocytes and collagen fibers were observed in the area of the vascular bed. The nuclei still contained some chromatin and the nuclear bodies were sometimes seen faintly. Septum-like structures gave the carcinoma tissue an organoid appearance. Round, oval and spindle-shaped cells of varying size were seen in the mesh-like spaces. Rosette-shaped structures were found mostly in the periphery. Trabecular, tubular, and muff-like structures are described. Among the bronchial adenomas, 2 cases showed amyloid deposits with infiltration in the affected area and metastases in the regional lymph nodes. Glassy aggregates were seen in the stroma; amyloid deposits were seen in internal organs only in one case of undifferentiated lung cancer. The stimulating factors in the construction of amyloid-like substances in oat-cell carcinoma and in carcinoid bronchial adenoma are probably biologically active hormones produced by these tumors.

- 1665 EARLY HISTOGENESIS OF TRANSPLANTED MOUSE MAMMARY GLANDS: II. WITHIN 96 HOURS FOLLOWING ISOGRAFTING. (E) Chew, E. C. (Dept. Anat. U. Western Ontario, London, Canada) and K. Hoshino. *Z Anat Entwicklungsgesch* 132(4):318-324, 1970.

Female mice were given ^3H -thymidine i.p. in 4 injections of 50 μg ; 3 hr later mammary duct segments were excised and implanted into recipient females and the distribution of the label was observed 24, 48, 72 and 96 hr after transplantation. Twenty-four and 48 hr after transplantation, many labeled and non-labeled epithelial cells were seen scattered in the adipose tissues at the transplantation sites, indicating dissociation of the transplanted mammary duct segments. By 72 hr the scattered labeled cells had formed aggregates which often contained non-labeled epithelial cells. Heavily-labeled cells undergoing mitosis were often found in these aggregates. By 96 hr after transplantation, many mammary ducts had multilayered epithelia. Only after 72 hr did the basement membrane appear to be complete with regenerating mammary ducts in advanced stages; how-

ever, by 96 hr all stages of regeneration of transplanted mammary tissue were seen. Each graft ultimately developed into 1 mammary gland only.

- 1666 MALIGNANT CELLS IN THE BLOOD OF EYE PATIENTS. (E.) Stanford, G. B. (U. Utah Med. Sch., Salt Lake City) and A. B. Reese. *Trans Amer Acad Ophthalmol Otolaryngol* 75(1):102-109, 1971.

Blood samples from 31 patients with intraocular tumors were passed through filters to detect malignant cells borne in the blood. The filters contained 400,000 holes/cm², and the holes measured 5 μ in diameter. Some patients had received no treatment, and some had undergone enucleation; ocular tumors in the patient sample included malignant melanoma and retinoblastoma. No malignant cells were found in the blood of untreated patients. Of the 18 patients undergoing enucleation for retinoblastoma, there were 3 positive blood samples; all 3 eyes proved to have choroidal invasion by the retinoblastoma. None of the malignant melanoma patients treated by enucleation showed malignant cells in their blood; but 1 malignant melanoma patient undergoing photocoagulation had a positive blood sample. Retinoblastoma cells in the blood were stained with 3er alanffy's acridine orange stain. The presence of malignant cells in the blood is not necessarily relevant for the prediction of the development or location of metastases; for malignant cells can pass to distant sites by routes other than the circulating blood.

- 1667 SUBCELLULAR FRACTIONATION OF MOUSE MYELOMA CELLS. (E.) Choi, Y. S. (Dept. Pediat., Minnesota, Minneapolis), P.M. Knopf and E. S. Lenné. *Biochemistry* 10(4):659-667, 1971.

A method is described for studying precursor-product relationships in subcellular components of a BALB/c mouse myeloma cell line by means of sucrose density gradient centrifugation and choline and leucine labeling. Repeated centrifugations revealed fraction I, rough membranes (RM), to be the principal constituent with fraction II, a mixture of RM, smooth membranes (SM) and free polyribosomes; fraction III had a variety of SM and some free monoribosomes, and fraction IV consisted of free proteins and membrane. Leucine-labeled cells revealed 80% of the light chain in fractions containing membranes, 95% of which were rough membranes of fractions I and II. The light chain of fraction II was kinetically different from that observed in fraction I. While the fractions obtained were heterogeneous, there was sufficient enrichment of rough membranes in fraction I and smooth membranes in fraction III to be useful for distinguishing kinetically and chemically the differentiating properties of the intracellular light chains.

- 1668 LIGHT AND ELECTRON MICROSCOPY OF LOW AND HIGH MALIGNANCY SUBLINES OF A RAT TUMOR. (E.) Ratcliffe, N. A. (Dept. Zool., U. Leicester, England), A. E. Williams and H. Smith. *J Nat Cancer Inst* 46(2):243-252, 1971.

Ascites and solid abdominal and s.c. tumors of high and low malignancy cell lines in the rat differed structurally, but showed no specific cellular structures associated with degree of malignancy. Electron microscopic examination of ascites tumors showed mitochondria concentrated in the Golgi region; these mitochondria had unusual buds involving both mitochondrial membranes and the cristae. Buds were never observed free in cytoplasm, but remained attached to the mitochondria. The mitochondria in solid abdominal tumors were generally larger than those in ascites tumors; solid abdominal tumors also had buds. The mitochondria of the s.c. solid tumors were similar to those of solid and ascites tumors. The minor differences observed between tumor cells of different malignancy were probably attributable to differing metabolic environments or to changes in cell surface charge. The mitochondrial buds were not thought to be associated with malignancy.

1669 ULTRASTRUCTURAL STUDY OF HUMAN PARATHYROID ADENOMA AND THE OCCURRENCE OF ABNORMAL CILIA IN THE ADENOMA CELLS. (E.) Polyzonis, M. B. (Theagenion Cancer Inst., Tessaaloniki, Greece). *Path Europ* 5(4):454-469, 1970.

Although the number of cilia found in normal parathyroid tissue cells by electron microscopy did not exceed 2 cilia/cell, the number of cilia in parathyroid adenoma tissue cells often numbered 4/cell. Both normal and adenomatous parathyroids were composed primarily of chief cells, but the normal cells had few ribosomes while the adenoma cells had many. In the adenoma cells, cilia were found lying singly or in groups within pericilliary vacuoles; some cilia were found lying in the intercellular spaces between cell membranes; in normal parathyroid tissue, cilia were never found lying free in intercellular spaces. Naked cilia were seen in the cytoplasm in some adenoma cells, but not in normal parathyroid cells. The association of cilia with immature cells may suggest that the overabundance of cilia in parathyroid adenoma cells is an expression of the immaturity of the tumor cells.

1670 SURFACE PROPERTIES OF HUMAN MELANOMA CELLS. (E.) Lapis, K. (U. Med. Sch., Budapest, Hungary) and M. Radnot. *Amer J. Ophthalmol* 71(3):740-750, 1971.

The surface properties of cells taken from 2 human ocular melanomas were examined by electron microscopy; ultrathin sections were stained with Luft's ruthenium red stain. Both tumors were composed of spindle-A cells and were thought to be benign. Cells showed a fairly even layer of stain on their surfaces, the layer's thickness varying from 14-20 nm. No nonspecific deposits of ruthenium red were seen. The stain did not enter the cells, but it did react with the limiting membrane of pinocytic vesicles which were either about to be detached from the plasmalemma or which had just been detached, but were still close to the cell membrane. Higher magnification revealed that deposits of stain sometimes accumulated where the parallel cell membranes approached each other, possibly representing the cell bridges observed with conventional electron microscope techniques. No stain was

seen on the membranes of degenerating cells; however, degenerating necrobiotic cells stained with ruthenium red usually showed a higher degree of electron-density than surrounding intact cells. The binding of the stain to cell components apparently results in increased electron density, for the limiting membranes of necrobiotic cells appeared to become permeable to the stain.

1671 TERATOMAS OBTAINED THROUGH EXTRAUTERINE GROWTH OF SEVEN-DAY MOUSE EMBRYOS. (E.) Damjanov, I. (Med. Fac. U. Zagreb, Yugoslavia), D. Solter, M. Belicza and N. Skreb. *J Nat Cancer Inst* 46(3):471-480, 1971.

Seven-day mouse embryos, transplanted under the kidney capsules of adult mice, produced teratomas which were either histologically well-differentiated and regarded as benign, or poorly differentiated and regarded as malignant. Small portions of 6 large (10-15 g in wt) and 4 small (1-3 g in wt) tumors were transplanted under the femoral fascia of syngeneic mice; 13 of 27 large tumor grafts grew in hosts, while none of the small tumor grafts took. Tumors obtained by retransplantation were microscopically similar to primary tumors arising after egg cylinder implantation. Large, well-differentiated teratomas contained many kinds of differentiated tissues stemming from all 3 germinal layers, including glia, ependyma, squamous epithelium, and bone. Differentiated tumors had the ultrastructural appearance of adult tissue, and included well-formed intracellular structures. The cytoplasm of poorly differentiated cells was typical of that of embryonal carcinoma; it showed abundant ribosomes, but lacked other organelles except for well-developed Golgi bodies, a few mitochondria and occasional rough endoplasmic reticulum material. Intermixed with these typical undifferentiated cells were other undifferentiated cells displaying some cytoplasmic specialization such as myofibrils, secretory granules and distorted microvilli. That the undifferentiated cells retained an embryonal appearance was thought to account for the continuous malignant growth of these embryonally derived teratomas.

1672 THE OCCURRENCE OF "NUCLEAR BODIES" IN BENIGN AND MALIGNANT HUMAN NEOPLASMS. (Ger.) Schremmer, C. N. (Robert Rossle Clin., German Acad. Sci., Berlin). *Arch Geschwulstforsch* 36(4):360-369, 1970.

The intranuclear structure of nuclear bodies found in benign and malignant human tumors was investigated by electron microscopy. The evaluation of the 143 tumors which consisted of epithelial and mesenchymal tumors was made on the basis of similar histological diagnosis. Nuclear bodies were found in 32 groups out of the 34 selected for their histological similarity, but these bodies were also seen in the stromal cells. No particular relationship could be found between the tumor type and the specific structure of the nuclear body. It was possible to conclude from the results that a common capacity for higher differentiation could be attributed to the nuclear bodies, although only in a very few tumors was there an overwhelming number of mature nu-

clear bodies. It was also concluded that the nuclear bodies are not likely to be of viral origin, but that they may be related to increased hormonal activity or to the introduction of toxic material.

- 1673 THE CONTROL OF GROWTH OF MAMMALIAN CELLS IN AXENIC CULTURE: THE ROLE OF CONFORMATION OF GROWTH REGULATORY PROTEINS. (E.) Tritsch, G. L. (Roswell Park Mem. Inst., New York St. Dept. Hlth., Buffalo), G. Grahl-Nielsen and J. A. Bell. *J Med* 1(2):90-100, 1970.

The effects of reversible urea denaturation, disulfide bond reduction and reoxidation, and intramolecular cross-linking on the growth regulatory activity of various calf serum proteins were investigated using a cell line derived from a small bowel carcinoma in the hamster. Reduction of disulfide bonds, accomplished by adding mercaptoethanol to the cell preparations, reduced the growth regulatory activity of the fetal calf serum in the hamster tumor cell culture. At levels of more than 0.1 mg calf serum protein/ml of culture, mercaptoethanol-treated cells showed densities decreasing to zero. Exposure of the proteins to 8 ml of urea followed by a removal of the urea resulted in enhancement of growth stimulatory activity in excess of the levels encountered in untreated calf serum. Reduction of disulfide bonds by mercaptoethanol treatment in the presence of urea practically abolished growth stimulatory activity. Intramolecular cross-linking of calf serum proteins with 1,5-difluoro-2,4-dinitrobenzene also produced materials practically devoid of growth regulatory activity. Conformation of serum proteins is apparently an important factor in determining their growth regulatory activity.

- 1674 STIMULATION OF CELL PROLIFERATION IN MOUSE KIDNEY BY ISOPROTERENOL. (E.) Malamud, D. (Massachusetts Gen. Hosp., Boston) and R. A. Malt. *Lab Invest* 24(2):140-143, 1971.

The effect of isoproterenol (IPR) injections on cell proliferation was investigated in the kidneys of mice given 0.025-11 mg of IPR i.p.; nucleic acid synthesis was followed by ^3H -thymidine and ^3H -uridine incorporation. Renal DNA synthesis reached its maximum 34 hr after a single injection of 9 mg of IPR; this maximum represented a 6-fold increase in DNA synthetic activity over that in kidneys not given IPR, but was smaller than the response seen in the parotid gland. DNA synthetic activity declined when doses of IPR exceeded 9 mg. Incorporation of ^3H -uridine into total renal RNA was depressed about 40% for 8 hr after injection of IPR, and then increased moderately above control values. IPR injection also produced a transient decline in ^{14}C -labeled phenylalanine incorporation into renal protein. Cellular hypertrophy, as measured by the ratio of RNA to DNA, was not elevated in kidney tissue after IPR injection as it was in the parotid gland. DNA synthesis was increased by combination doses of IPR and theophylline more than it was increased by IPR alone, suggesting that cyclic 3', 5'-adenosine monophosphate was implicated in the initiation of cell proliferation by IPR.

- 1675 GROWTH OF MULTICELL SPHEROIDS IN TISSUE CULTURE AS A MODEL OF NODULAR CARCINOMA. (E.) Sutherland, R. M. (Ontario Cancer Treatment Res. Fdn., London, Canada), J. A. McCredie and W. J. Inch. *J Nat Cancer Inst* 46(1):113-120, 1971.

Chinese hamster V79 lung cells in suspension culture were grown to study the effects of nutrition and oxygenation on growth as well as the effect of drugs on radiation through autoradiography and photomicrographs. Small aggregates of 5-10 cells formed during the initial hours in culture and accounted for the rapid increase in mean volume of the spheroids which increased directly with the initial cell number and with the concentration of fetal calf serum. Subsequent growth which occurred by cell division to form multicell spheroids was exponential for 4 days, decreased and then approached a horizontal asymptote on the 9th day. Cells were similar until spheroid reached a diameter of about 200 μ ; then pyknotic cells appeared centrally and centrinodular necrosis developed in larger spheroids. Three distinct zones were noted in continuous labeling with ^3H -thymidine; mitotic cells were uniformly distributed until the spheroid reached a diameter of 150 μ when the mitotic index began to decrease from 3.1% to reach 0.7% at 370 μ . Electron micrographs showed cellular communication to be similar to that of organized tissue with tight, intermediate and desmosome junctions visible. The multicell spheroid has several advantages as an *in vitro* tumor model since its shape facilitates the use of mathematical equations for calculating the number of cells and diffusion of metabolites.

- 1676 MORPHOGENIC AND MITOGENIC EFFECTS OF PROLACTIN ON RAT MAMMARY GLAND *IN VITRO*. (E.) Dilley, W. G. (Dept. Zool., U. California, Berkeley). *Endocrinology* 88(2):514-517, 1971.

The effects of insulin (25 U/mg) and prolactin (28 U/mg) on mitotic activity was investigated in rat mammary gland cultures of 0-5 days. After 1 day in culture, no alveolar activity was observed in cultures of mammary cells treated with insulin or with prolactin. However, after 5 days insulin-treated cultures had attained alveolar grade 0.9, and cultures treated with both insulin and prolactin had attained alveolar grades 2.5-3.0. On day 1, cultures treated with insulin only showed 1.0-1.3% mitotic figures, and cultures treated with insulin and prolactin showed 2.0-2.7% mitotic figures. On day 5, insulin-treated cultures had 0.2-0.3% mitotic figures, and cultures treated with insulin and prolactin showed 1.1-1.2% mitotic figures. Pattern of DNA synthesis in cells cultured with insulin alone were not markedly altered by the addition of prolactin. In epithelial cells cultured with insulin and prolactin, DNA synthesis showed a log-dose response to increasing doses of prolactin. Results were reliable only for epithelial mammary gland cells and not for fibroblasts or for total mammary gland cells. Prolactin appeared to be mitogenic for epithelial cells.

- 1677 VARIATION OF THE TRANSMEMBRANE POTENTIAL LEVEL AS A BASIC MECHANISM OF MITOSIS CONTROL. (E.) Cone, C. E., Jr. (Langley Res. Ctr. Hampton, Va.). *Oncology* 24(6):438-470, 1970.

correlation between mitotic activity and the transmembrane electrical potential (E_m) of cells is well established; mitotic quiescence is generally associated with high E_m values, mitotic activity with low E_m values. The correlation is especially striking in tumor cells; the E_m of myosarcoma cells was found to be -10 mV, as compared to E_m value of -90 mV for adjacent normal cells. Changes in the cell membrane accompanying malignant transformation and adaptation of living cells to culture conditions may also be causally associated with the observed changes in cell membrane E_m in malignant cells. On the basis of the observed correlation between E_m and mitosis, a model was proposed according to which intracellular ionic conditions associated with changing E_m values regulates DNA synthesis in the cell and other preconditions for mitosis. The model's plausibility was supported by findings on record that imposition of intracellular ionic conditions approximating those at an E_m level of -70 mV (equivalent to the E_m of a nondividing nerve cell) reversibly blocked DNA synthesis and mitosis *in vitro*. The model postulated sets forth a system of feedback circuits operating in the cell to link those mechanisms in the cell membrane which control E_m with features of cellular metabolism and with environmental osmotic factors, including surface contact with other cells and the presence of hormones in the vicinity of the cell. 1678 EFFECTS OF ACTINOMYCIN D AND PUROMYCIN ON DIFFERENT PHASES OF THE LIFE CYCLE OF PHA-STIMULATED LYMPHOCYTES *IN VITRO*. (E.) Stolzmann, W. M. (Med. Acad. Poznan, Poland). *Bull Acad Pol Sci* 18(10):663-668, 1970.

The sensitivity of different phases of the cell cycle to actinomycin D and puromycin was studied in cultures of phytohemagglutinin (PHA)-stimulated peripheral lymphocytes in media with methotrexate and adenosine. Actinomycin D (0.1 and 1.0 μ g/ml of culture) added 9-12 hr before the start of DNA synthesis with 14 C-thymidine caused a decrease of the number of labeled cells to approximately 50%; when added 16 hr prior to the start of DNA synthesis this decrease did not occur. Similar results occurred with puromycin. Actinomycin D and puromycin added to cultures at the time of reversal of DNA synthesis did not affect the number of labeled cells during the last 8 hr of the S period. However, after 2 hr of incubation, the grain count/cell was reduced to 50% of the control value. In a third group of cells in which reversal of the inhibitory effects of methotrexate was followed by addition of actinomycin D, suppression of cell division occurred during the subsequent 24 hr. The effect of actinomycin D was more pronounced during the S period. Results suggest during euchromatin replication. Results suggest that at least 2 actinomycin D- and puromycin-sensitive mechanisms control the DNA synthesis in these stimulated lymphocytes.

1679 ELECTRON MICROSCOPIC AND CHROMATOGRAPHIC STUDY ON MALIGNANT TUMOR CELLS INVADING FAT CELLS. (Ger.) Wessel, W. (Path. Inst. U. Bonn, Germany). *Verhandl Deutsch Ges Path* 54:454-458, 1970.

The invasion of tumor cells into the surrounding fat tissue was investigated in 10 medullary solid mam-

mary carcinomas. The infiltration into the fatty tissue was marked by collagen formation. The electron microscopic demonstration of tumor invasion into the fat alveoli showed the peripheral reticulum to consist of numerous irregularly formed processes with hyaloplasm. The appearance of the tumor cells suggested high surface motility compared to normal cells which are limited by the basal membranes. Two invasion factors appeared to be the high motility of the tumor cell membranes which inhibited the formation of basal membranes and thus were in contact with the reticular network, and tumor cell phagocytosis of the fat cells. The latter was not seen in all cases. The fatty globules were seen to be broken up into smaller particles in the cytoplasm of the tumor cell and was shown to be unchanged by chromatographic techniques.

1680 LYSOSOMAL CHANGES AND ENHANCED METASTATIC GROWTH: AN EXPERIMENTAL STUDY OF THE EFFECTS OF SOME NON-IONIC SURFACTANTS. (E.) Carter, R. L. (Roy. Cancer Hosp., London, England), M. S. C. Birbeck and J. A. Stock. *Int J Cancer* 7(1): 34-49, 1971.

The effects of treatment with each of 4 non-ionic surfactants on tumor development and metastasis were investigated in female golden hamsters implanted with metastasizing lymphoma or non-metastasizing lymphoma in the flank. About 2-15 days after tumor implantation, hamsters were given i.p. injections of either Triton W-1339 detergent (1,000 mg/kg), poly 15 (1,000 mg/kg), poly 30 (1,500 mg/kg) or macrocyclon (850 mg/kg). Treatment with the detergents enlarged the size of hepatocytic lysosomes; normal lysosomes, which measured 0.2 μ , were enlarged approximately 10-fold. The detergents produced a moderate fall in tumor wt (untreated control hamsters' tumors had mean wt of 12 g, while mean wt for tumors of hamsters given Triton and macrocyclon were 7.2 and 6.8 g, resp.). However, detergent-treated animals showed increased metastatic spread compared to controls. While metastases involving the axillary nodes, anterior mediastinum, liver and mesenteric nodes occurred in many hamsters both treated and untreated, treated animals also showed metastatic involvement in the posterior mediastinum, lungs, spleen or ovaries. Metastatic growth in control hamsters was focal, while in detergent-treated animals metastatic growth was diffuse. Both treated and untreated hamsters showed high liver/body wt ratios, high liver acid phosphatase activity, and liver lysosomal damage; however, these changes were more pronounced in treated hamsters than in controls. The mechanism of increased metastatic spread in detergent-treated hamsters may be due to the lysosomal damage caused by the detergents in lysosome-rich organs such as the liver. No metastasis was caused by detergents with the non-metastasizing lymphoma.

1681 SIGNIFICANCE OF THE SIZE DISTRIBUTION OF BLOODBORNE METASTASES. (E.) Douglas, J. R. S. (Roy. Newcastle Hosp., New South Wales, Australia). *Cancer* 27(2):379-390, 1971.

A model based on the notion that metastasis is a random process in which events may occur from the

moment of initial transformation of the primary focus of tissue into malignant tissue has been constructed to provide a means for explaining the biological behavior of metastasizing neoplasms. In postmortem examination of organs, no indication of abrupt augmentation of the rate of metastasis formation was observed as may be expected if the primary neoplasm gained in activity on proceeding from one stage of anatomical spread to another. Where diameters of the metastatic spheres were greater than the thickness of the sections, marked deviation from a straight line was noted on plotted measurements. Evidence of a decline in metastases formation to almost complete suppression was noted in 3 cases treated by tumor excision and 1 by therapeutic radiation. Typical plots appeared to result in a rectilinear curve for early metastases with subsequent deviation and trend toward formation of fewer metastases.

- 1682 STUDIES ON THE MECHANISMS OF INVASION IN CANCER: II. *IN VIVO* EFFECTS OF A FACTOR CHEMOTACTIC FOR CANCER CELLS. (E.) Ozaki, T. (Kumamoto U. Med. Sch., Japan), K. Yoshida, K. Ushijima and H. Hayashi. *Int J Cancer* 7(1):93-100, 1971.

Although tumor-free rats failed to respond to injections of a chemotactic substance for cancer cells isolated from tumor tissue, rats previously inoculated with 2.5×10^5 rat ascites hepatoma cells/ml showed extravascular emigration of circulating tumor cells following an injection of 50 or 70 μ g of cancer cell chemotactic substance. Emigration of tumor cells was observed within 24 hr of injection, and by 72 hr postinjection, the number of emigrated cancer cells had markedly increased at the injection site, the proliferation being especially intense in the subcutaneous tissue. By 11 days postinjection, cancer cells had invaded the muscles under the injection sites to form a metastatic secondary tumor. No emigration of polymorphonuclear leukocytes was seen. Injection of the chemotactic tumor cell factor did not increase vascular permeability; however, injection of permeability factors isolated from tumor tissues, and of histamine or bradykinin failed to produce tumor-cell emigration. Injection of a factor chemotactic for polymorphonuclear leukocytes produced pronounced leukocyte emigration from the venules followed by infiltration of the cells throughout the skin tissue, but did not cause cancer cell migration. These results suggest that malignant invasion may involve a chemotactic factor.

- 1683 SEQUENCE OF EVENTS IN EXPERIMENTAL METASTASES OF WALKER 256 TUMOR: LIGHT, IMMUNO-FLUORESCENT, AND ELECTRON MICROSCOPIC OBSERVATIONS. (E.) Jones, D. S. (Dept. Path., U. Western Ontario, London, Canada), A. C. Wallace and E. E. Fraser. *J Nat Cancer Inst* 46(3):493-504, 1971.

Young adult rats were given tail-vein injections of Walker 256 tumor cells and killed 2 min-72 hr later, at which time the spread and disposition of the tumor cells were observed. Staining of sections of tissue was with hematoxylin-eosin, Lendrum's stain for fibrin, and immunofluorescent staining for fibrin. At

2 min post-inoculation, light and electron microscopic examination detected tumor cells in groups of 1-6 in pulmonary arteries and capillaries and in small arterioles; all cells were intravascular, and partially or entirely surrounded by a pink meshwork which stained as fibrin with Lendrum's stain. Platelets could be seen in this meshwork. Immunofluorescent stains gave strong reactions for fibrin. From 1-49 hr after inoculation, the number of tumor cells was seen to decline steadily; however, after 49 hr post-inoculation, tumor cells increased rapidly, and by 72 hr there were 3 times the number of cells seen at 48 hr. Numbers of platelets associated with the tumor cells declined with time from inoculation; fibrin also decreased. The endothelial lining was breached by tumor cells, and by 24-48 hr the cells were clearly perivascular and lying in apposition to the connective tissue.

- 1684 ANNULATE LAMELLAE IN CULTURED HUMAN NEUROBLASTOMA CELLS. (E.) Goldstein, M. N. (Washington U. Sch. Med., St. Louis, Mo.). *Cancer Res* 31(3):209-213, 1971.

Distinctive annulate lamellae were observed in cultures of neuroblasts prepared from tissue explants from human neuroblastomas. Tissue samples were taken from tumor metastases in the lymph nodes of 3 children under 5-yr-old and from an abdominal tumor from a fourth child. Cells from the cultures were prepared for electron microscopy after 10-160 days in culture. The immature neuroblasts contained scant cytoplasm, rough endoplasmic reticulum and many free ribosomes. Nuclear pores were seen in sections cut tangentially to the nuclear surface, and arrays of annuli were seen in the cytoplasm of about 5% of the neuroblasts, and their morphology corresponded to that of the nuclear pores. Annuli were associated with lamellae, a series of undulating membranes which were continuous with the annuli. The annulate lamellae may be the result of a relaxation of the mechanism responsible for new nuclear membrane synthesis.

- 1685 NEPHROBLASTOMA: A CHROMOSOMAL STUDY. (Fr.) Rousseau, M. F. (Paris, France), M. Laurent and C. Nezelof. *Ann Anat Path* 15(4):399-414, 1970.

In a chromosome analysis of 3 cases of nephroblastoma in human infants, the numerical anomalies were examined by means of a histogram of the distribution of mitoses as a function of their chromosome number and by the calculation of the mean chromosomal population of aneuploid mitoses; karyotype structural anomalies were studied, and supplementary chromosomes were classified. From the study of short term cultures, 334 mitoses were grouped and analyzed. The karyotype study of these cases showed either a diploidy with a slight tendency to polyploidy, or a aneuploidy with a homogeneous distribution about the

mode of 53 chromosomes. Structural anomalies were rare and no particular chromosome feature could be singled out. The chromosomal results of the short term cultures after 7, 13 and 22 days of culture led to the conclusion that there was no predominant selective effect. The results confirm reports found in the literature that a tumor type is not characterized by a common variant, and the karyotypes of the same tumor type are not generally identical; anormal karyotype can be found in a cell with a neoplastic character.

- 1686 ADDITIONAL EVIDENCE FOR CHROMOSOME ABNORMALITIES IN THE ERYTHROID PRECURSORS IN ACUTE LEUKAEMIA. (E.) Krogh Jensen, M. (U. Hosp. Copenhagen, Denmark) and S. A. Killmann. *Acta Med Scand* 189(1-2):97-100, 1971.

Karyotype studies were performed on bone marrow aspirates from 5 leukemia patients to detect chromosome abnormalities in these cells. The patients included 4 males and 1 female with myeloblastic leukemia, acute erythroleukemia, and promyelocytic leukemia. Two patients had hyperdiploid cell lines, 1 had a hypodiploid line, and 2 had pseudodiploid cell lines. In 1 instance, a minute acentric fragment was observed. The percentage of erythroid metaphases in leukemic marrow was found to be markedly higher than the percentage in marrow of normal subjects. From 16-62% of the mitotic figures in the bone marrow aspirates from the leukemia patients were erythroid, while the percentages of normal metaphases ranged from 0-22%. Chromosome abnormalities apparently are not confined to blastic cells in acute myeloid leukemia, but are also to be found in erythroid precursor cells. It was suggested on the basis of these findings that acute myeloid leukemia is a general disease of the hemopoietic system rather than a disease of the granulocytic cell line only.

- 1687 MULTIPLE CELL ORIGIN OF HEREDITARY NEUROFIBROMAS. (E.) Fialkow, P. J. (Dept. Med., U. Washington, Seattle), R. W. Sagebiel, S. M. Gartler and D. L. Rimoim. *New Eng J Med* 284(6):298-300, 1971.

Tumors and overlying skin from 2 Negro women with a total of 14 hereditary neurofibromas were examined to determine whether the tissues contained both A and B types of glucose-6-phosphate dehydrogenase. In females carrying both the A and B genes at the X-linked glucose-6-phosphate dehydrogenase locus, single cells express the activity of only 1 or the other gene. Therefore, it was thought that neoplasms arising from a single cell should exhibit only type A or B enzymes; the detection of both enzymes would indicate that the neoplasm had a multiple cell origin. Electrophoresis showed that both the A and B enzymes were present in each of the 14 tumors and in all specimens of overlying skin. Contamination of the tumor and overlying skin tissues with normal tissue was ruled out, and it appeared that the finding of the double enzyme phenotype in these subjects was a reliable indication of a multiple cell origin for the hereditary neurofibroma. The initial tumorigenic event associated with the development of neurofibroma may affect a few cells

which subsequently alter adjacent cells, or it may affect large numbers of cells simultaneously.

- 1688 MACROGLOBULINEMIA OF WALDENSTRÖM AND THE CHROMOSOMAL MORPHOLOGY. (E.) Goh, K. O. (Sch. Med. Dent., U. Rochester, N. Y.) and S. N. Swisher. *Amer J Med Sci* 260:237-244, 1970.

Peripheral leukocyte cultures and bone marrow preparations from patients with Waldenström's macroglobulinemia were subjected to cytogenetic examination. Karyotypes from 3 patients showed that 43% of metaphases contained an abnormally large chromosome, larger by 9-33% than the largest chromosome in the complement. The large chromosome was found to replace either the 1, 2 or 3 chromosome in group A. Large chromosomes were also found in 40% of metaphases from leukocytes of normal persons cultured with plasma from patients with Waldenström's macroglobulinemia. Only 10% of metaphases from normal control cultures showed the large chromosome. The abnormally large chromosome may have resulted from the different effects of colchicine on the cells of the Waldenström's macroglobulinemia patients. Colchicine exposure, in turn, may have resulted in one of the normal A chromosomes being coated with a large molecular-wt protein.

- 1689 GONADOBLASTOMA IN A PHENOTYPIC FEMALE WITH 45,X/47,YYY MOSAICISM. (E.) Sune, M. V. (Inst. Natural Sci., Fed. U. Rio Grande do Sul, Porto Alegre, Brazil), J. V. Centeno and F. M. Salzano. *J Med Genet* 7(4):410-412, 1970.

A case report of gonadoblastoma, a rare ovarian dysgenetic tumor, in a woman having a karyotypic picture previously unrecorded in connection with this condition is presented. The left ovary of the subject, a 21-yr old woman, was composed of cords of large round cells with vacuolated cytoplasm, the general aspect of which was similar to dysgerminoma. Other components of the affected ovary included cells with small oval nuclei showing calcified irregular concretions and fibrous stromas with nests of Leydig-like cells. Chromosome counts of peripheral leukocytes showed modal chromosome numbers of 45 and 47; and karyotype analysis of cells having these chromosome numbers showed a mosaicism of the 45,X/47,YYY type, which is unique in gonadoblastoma patients.

- 1690 45,X,G-,Ph¹ + CELL LINE IN BONE-MARROW AND BLOOD OF A CML AFFECTED MALE. (E.) Serra, A. (Catholic U. Sch. Med., Rome, Italy), S. Sargentini, C. Patrono, A. Ferrara and V. Laghi. *Ann Genet* 13(4):239-243, 1970.

Cytogenetic studies were performed on bone marrow and peripheral blood cells of a male patient with chronic myelogenous leukemia in whom bone marrow cells were found to contain the Ph¹ chromosome and to lack 1 of the G group chromosomes. In this case, chronic myelogenous leukemia was diagnosed on the basis of physical symptoms, hyperplastic bone marrow, and prevalence of myelocytes. Cytogenetic studies showed 45 chromosomes in both the bone mar-

row and blood cells and only 4 G group chromosomes in the blood cells and in 45% of the bone marrow cells. Ph¹ chromosome could be demonstrated clearly in 86 cell preparations from bone marrow, and peripheral blood cells showed a similar karyotypic pattern. It was speculated that the missing chromosome might be the Y, but this could not be ascertained.

- 1691 DNA REPLICATION PATTERNS IN CHROMOSOMES OF SEVERAL TRANSPLANTABLE ASCITES HEPATOMAS OF THE RAT. (E.) Sasaki, M. (Fac. Sci. Hokkaido U., Sapporo, Japan). *J Nat Cancer Inst* 46(1):25-35, 1971.

DNA replication patterns of transplantable ascites tumor cells in seven aneuploid strains of rats were investigated by means of short-term *in vitro* incubation with tritiated thymidine autoradiography. Labeled interphase cells ranged from 30-96%; the increase was proportional to incubation time, and a similar pattern was noted in metaphase cells with the exception of AH-13 and AH-13 and AH-41c strains in which the relation was inconsistent. In 7 of 11 cells analyzed in AH-130 1 telocentric element at the 847th generation was relatively late replicating. In 70% of the cells at least 1 or 2 elements of some of the largest telocentric members resembled the largest telocentric pair of the normal karyotype, and generally in early replicators 1-3 elements in the small metacentric group and 1-4 elements in the telocentric group were unlabeled in about 40-60% of the cells. In AH-41c, the tumor was characterized by the presence of large metacentric and medium-sized metacentric markers and a small telocentric marker corresponding in size and shape to the Y chromosome. AH-7974 karyotype was characterized by 2 minute dotlike elements and several abnormal submetacentric markers with Y-like elements in all 10 cells studied; AH-414 had 3 distinctive markers including a large metacentric, a minute, and a medium-sized subtelocentric with 2 prominent secondary constrictions on its long arm, whereas the karyotype of AH-272 had a large metacentric, subtelocentric and a medium-sized metacentric with both tumors showing relatively late or early segmental patterns. Replicatory features of chromosomes in transplantable ascites hepatomas are different from normal ones and the abnormal patterns may in some way be related to the drastic numerical and structural changes of chromosomes in the tumors.

- 1692 CYTOLOGICAL AND CYTOGENETICAL STUDIES ON BRAIN TUMORS: II. HYPERDIPLOIDY, A RARE EVENT IN HUMAN PRIMARY MENINGIOMAS. (E.) Zankl, H. (Max Planck Inst. Psychiat., Munich, Germany), H. Singer, K. D. Zang, H. Büscher and W. Kofler. *Humangenetik* 11(3):253-257, 1971.

The chromosomal findings among 70 human meningiomas were cytogenetically investigated through biopsy of brain tissue. The great majority of meningiomas showed an increasing hypodiploidy beginning with the loss of a G-group chromosome. Two tumors with a modal chromosome number of 53 (50-54) showed similar histological appearance representing a special

type of fibromatous meningioma in which an excess of D chromosomes was constant. The loss of G-group chromosomes could not be established in these tumors. In 1 meningioma, a true C-trisomy seemed to be present with the metacentric extra chromosome showing a marked secondary constriction at the proximal part of its long arm and another at its distal part. Findings in these 70 meningiomas indicated that the preferred chromosomal deviation consisted in the loss of a G-group chromosome with or without subsequent loss of further chromosomes.

- 1693 CHROMOSOMAL ANALYSIS OF LYMPHOBLASTOID CELL LINES AFTER HETEROSEXUAL COCULTIVATION WITH BONE MARROW FIBROBLASTS. (E.) Benyesh-Melnick, M. (Baylor Coll. Med., Houston, Tex.), M. Macek, E. H. Seidel and V. Mackova. *J Nat Cancer Inst* 46(2):369-382, 1971.

Chromosomal studies were carried out on lymphoblastoid cells from peripheral blood leucocytes and bone marrow of 10 female patients, 3 with acute leukemia and 7 with infectious mononucleosis; the cells were maintained in cocultivation with diploid human bone marrow fibroblasts from males. Karyotype studies of the leukemia and mononucleosis cell lines showed them to consist of 3 groups according to karyotype characteristic. One group showed a conventional 46,XX karyotype and included only infectious mononucleosis cell lines. Other groups showed marker chromosomes with a submedian centromere, a pseudodiploid clone, trisomy C, and polysomy C. T cell cultures were studied over 20-174 serial passages; the sex of the cell lines was found to have remained female. This suggested that the fibroblasts in which the lymphoblastoid cells were maintained had a feeder layer function, and were not transformed by an agent in the lymphoblastoid lines. Heteroploidy developed only in cells from patients with mononucleosis.

- 1694 REGULATION OF PHENOTYPIC EXPRESSION IN CROWN-GALL TERATOMA TISSUES OF TOBACCO. (E.) Meins, F., Jr. (Rockefeller U., New York, N.Y.). *Develop Biol* 24(2):287-300, 1971.

The physiological basis for stability of the teratoma phenotype in tobacco crown-gall tumors through developmental variants derived from cloned teratoma cells and phenocopies of the variant forms through chemical treatment of teratoma tissues in culture is described. Two phenovariants of cloned teratoma tissues were isolated as highly localized outgrowths with distinct morphology at the edge of the parent teratoma tissues and were propagated for 8 yr without reversion to the parent phenotype. Phenovariant A grew as a flattened glistening white sphere composed of densely packed filamentous cortical cells surrounding a tan core of parenchymal cells, where phenovariant B grew as a totally unorganized callus composed of parenchyma cells devoid of vascular elements or well-defined meristematic centers, shoots or leaves. Neither variant synthesized chlorophyll when grown under conditions of continuous lighting and variant A grew more slowly while variant B grew slightly faster than the parent organized tissue.

Glutamine-induced variation resulted in a phenotype indistinguishable from the snowy phenovariant with an occasional reversal to the parent organized phenotype depending on time between transfers and number of transfers on glutamine-containing medium. Malic acid, α -ketoglutaric acid, and ammonium ion promoted organized development while glutamine, glutamic acid, proline, γ -aminobutyric acid, aspartic acid and asparagine induced persistent changes to the snowy phenotype. These findings suggest that the reversible reaction of α -ketoglutaric acid and ammonium ion to form glutamic acid is a key site in regulating phenotypic expression in tobacco teratoma tissues.

- 1695 SPONTANEOUS CHOLANGIOMAS IN STRAIN C3H-A^{VY}AVYFB MICE AND IN THEIR HYBRIDS. (E.) Vlahakis, G. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and W. E. Heston. *J Nat Cancer Inst* 46(3):677-638, 1971.

Cholangiomas associated with bile ducts were seen in the livers of strain C3H-A^{VY}FB mice and in (C3H-A^{VY}FB X BALB/c) hybrids. The cholangiomas were seen only in animals which had also developed hepatomas. C3H-A^{VY}FB females produced 23 cholangioma-bearing mice out of 296 mice observed. Early cholangiomas often involved the epithelia of bile ducts in the liver; in one case, the cholangioma was seen in a bile duct which was contained in a hepatoma. Other early lesions appeared as proliferation of the small bile ducts. Better differentiated cholangiomas appeared to form ducts or acini. One of the cholangiomas was found to be malignant; it metastasized to the lung, and successfully underwent isogenic transplantation in 3 mice. The viable yellow gene and the lethal yellow gene were thought to be associated with the development of cholangiomas in these mice; these genes may have increased the susceptibility to cholangioma development of the mice.

- 1696 CARCINOMA OF THE LARGE INTESTINE WITH SURVIVAL IN A CHILD OF NINE AND IN HIS FATHER: A STUDY OF CARCINOMA OF THE COLON WITH PARTICULAR REFERENCE TO CHILDREN. (E.) Pemberton, M. (Enfield Group Hosp., England). *Brit J Surg* 57(11):841-846, 1970.

A boy presented to the hospital with abdominal pain which was found to have been caused by a large adenocarcinoma of the colon infiltrating through the wall and involving the small bowel and the abdominal wall. The tumor was removed surgically, recurred about a year later, and was excised; the patient recovered satisfactorily. The patient's father, aged 43, also had a rectal carcinoma infiltrating the muscle coat; the tumor was removed, and the father recovered completely. In the case of the first patient, the colonic condition was originally misdiagnosed as apendicitis, and the frequency of mistaken diagnoses associated with colorectal carcinomas was thought to be high. Long-term survival in a child having colonic carcinoma was found to be rare in a review of the literature. It was thought that in cases of colorectal carcinoma in which the tumor infiltrates but does not metastasize, the prognosis may be favorable. Although there was no positive evidence for a genetic basis for

this father-son occurrence, cancer development in a young person suggests the possible involvement of hereditary factors.

- 1697 BURKITT'S LYMPHOMA WITH FEMALE KARYOTYPE IN AN AFRICAN MALE CHILD. (E.) Manolov, G. (Inst. Genet., U. Lund, Sweden), A. Levan, J. S. Nadkarni, J. Nadkarni and P. Clifford. *Hereditas* 66(1):79-100, 1970.

A Burkitt's lymphoma tumor with a female karyotype was observed in a male African child who died of a left maxillary tumor with kidney involvement at age 9. Six chromosome fixations prepared from biopsies of the tumor showed a female karyotype for the tumor cells. Chromosome numbers recorded in the fixations were usually 45 or 46, with some counts as low as 43 and some as high as 48. Of 90 karyotype analyses available, 88 belonged to the tumor; of these, 87 were diploid, and 1 was hypotetraploid. The remaining 2 karyotypes were of bone marrow cells, and showed normal male karyotype. The C group of chromosomes had 16 chromosomes and the G group had 4, with the Y chromosome missing. Autoradiography showed 1 late-replicating X chromosome in the tumor cells. The chromosome lacking in the G group was thought to be the Y; no typical Y chromosome was ever seen in the tumor cells. The possibility that the tumor cell cultures had been contaminated, resulting in a female karyotype, was eliminated by the presence in all fixations of a characteristic small marker G chromosome. Transmission of cells from mother to child might account for the female karyotype tumor found in a male patient in this case.

- 1698 REGIONAL BIOENERGETIC EVENTS IN THE EXPERIMENTAL GLIOBLASTOMA: A QUANTITATIVE HISTOCHEMICAL STUDY. (E.) Kirsch, W. M. (U. Colorado Med. Sch., Denver) and D. R. Schulz. *J Neurosurg* 34(3):448-451, 1971.

Biochemical events occurring in a chemically induced murine glioblastoma during anaerobiosis were observed. The tumor responded to deprivation of oxygen more sluggishly than normal mouse brain tissue. Throughout the area of the glioblastoma, the production of lactate far exceeded expected levels; despite prolonged ischemia, all zones of the tumor continued to generate lactate and to maintain low but significant levels of ATP, suggesting the mobilization by the tumor of an unsuspected reserve of energy. A decrease in pentose nucleic acids was observed during prolonged ischemia in all zones of the tumor, the decrease was more pronounced in the periphery of the tumor than in its center. This finding suggests that the source of the hypothetical reserve energy in the tumor may be the nucleic acids, perhaps tumor RNA. Since the glioblastoma was virtually without capillaries, it was thought that nutrition of the tumor occurred exclusively from its surface.

- 1699 A CASE OF BURKITT'S TUMOR IN ITALY. (E.) Grampa, G. (U. Milan Med. Sch., Italy), M. Bestetti-Bosisio, F. Bergamini and P. Arlotta. *Path Europ* 5(4):470-484, 1970.

An 11-yr-old Italian boy presented to the hospital with large tumors of the oral cavity and a slight protrusion of the right eye. Biopsy of the tumor material confirmed the diagnosis of stem cell Burkitt's lymphoma, which was thought to be the first such diagnosis in Italy. Enlargement of the left testis due to tumor tissue, and a nodule at the root of the nose were additional features of the case which proved fatal 5 months after onset of symptoms. Tumor tissue was found to have invaded the brain on autopsy. Cytogenetic analysis of tumor cells showed a chromosome number ranging from 42-49, and the presence of an extra long acrocentric chromosome replacing one D-chromosome, and an extra C-chromosome with the characteristics of a number 10 chromosome. Inoculation of tumor cells in PPLO media produced a mycoplasma strain, later identified as *Mycoplasma orale*.

- 1700 ACHALASIA AND CARCINOMA OF THE ESOPHAGUS. (E.) Wychulis, A. R. (Mayo Grad. Sch. Med., Rochester, Minn.), G. L. Woolam, H. A. Andersen and F. H. Ellis, Jr. *JAMA* 215(10):1638-1641, 1971.

The development of carcinoma confirmed by esophageal roentgenograms and histologic analysis in patients treated for achalasia (1,318) from January, 1935 to January 1967 has been evaluated. Twelve men and one woman, ranging in age from 36 to 81 yr, developed esophageal carcinoma; they had been treated initially by simple dilatation with metal sounds from 1 to 12 times while 6 had also undergone hydrostatic dilatation 1-9 times; 3 had been treated surgically. In 10 of 12 patients with dysphagia an increase in intensity of symptoms was noted with concomitant hematemesis or melena or both. Malignant tumors arose at all levels of the esophagus and were diagnosed as 8 grade 3 (Broders') squamous cell carcinomas, 2 grade 1 verrucous squamous cell carcinomas and 1 grade 4 adenocarcinoma involving the cardia of the stomach. Duration of achalasia prior to diagnosis of carcinoma averages 28 yr. The incidence of carcinoma in this series of patients with achalasia is much lower than that reported by others, but is higher than the incidence of esophageal carcinoma in the general population, ranging from 16-84/100,000/yr as compared to 6/100,000/yr for the general population. Prognosis of esophageal carcinoma which arises from achalasia is poor because the extent and spread of the growth usually preclude the possibility of a curative surgical procedure.

- 1701 THE TRANSMISSION OF TUMORS INDUCED IN COCKROACHES BY NERVE SEVERANCE. (E.) Nayar, K. K. (Dept. Zool., Kerala U., Trivandrum, India), E. Arthur and M. Balls. *Experientia* 27(2):183-184, 1971.

Cell-free extracts from tumor tissue produced in the salivary glands, gastric ceca and receptacles of cockroaches by transection of the recurrent nerve

were injected into the hemocoel of normal cockroaches via the prothorax or abdominal tergite; cockroach nymphs in the final instar also received injections. Pronounced hemocyte invasion was observed in the salivary glands of most insects given injections of cell-free extract; hemocyte accumulation in the salivary glands was most pronounced in nymphs and in adults given tumor filtrate (450 nm filter); in general, nymphs developed more pronounced hemocyte accumulations than adults. Normal tissue extract produced no hemocyte invasion. Cytoplasmic granules which may have been hemocyte remnants were seen in the hemocytes accumulated in the glands.

- 1702 STUDIES OF THE AFFINITY OF NUCLEAR MATERIAL FOR UROPORPHYRIN: I. THE NUCLEI AND CHROMOSOMES OF EHRICH ASCITES TUMOR CELLS. (E.) Miya, K. (Dept. Med., U. Minnesota, Minneapolis), G. R. Hartmann, W. Runge and C. J. Watson. *Biochem Med* 4(5-6):391-402, 1970.

The uptake of uroporphyrin I *in vivo* and *in vitro* the nuclei and chromosomes of Ehrlich ascites tumor cells was studied in female mice of the Heston strain utilizing fluorescence microscopy with dark-field illumination or phase-contrast microscopy. The majority of the cells and particularly the nuclei exhibited fluorescence following i.p. injection of uroporphyrin I, with strong fluorescence exhibited in the ascitic fluid during the first 12 hr. In colchicine-treated animals, striking red fluorescence of metaphase chromosomes was most easily seen. The uroporphyrin was excreted completely from the ascitic fluid 20-24 hr after injection; however, most nuclei continued to fluoresce quite strongly up to 48 hr. When the agent was complexed with zinc, the results were similar to those of the free chemical. The nuclei of some cells from mice receiving uroporphyrin *in vivo* fluoresced more strongly than did the nuclei themselves.

- 1703 PARTITION OF ENERGY EXPENDITURE BETWEEN HOST AND TUMOR. (E.) Morrison, S. D. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.). *Cancer Res* 31(2):98-107, 1971.

Partition of energy metabolism between host and Walker tumor have been analyzed in adult male Sprague-Dawley rats utilizing oxygen consumption-carbon dioxide production monitoring. Total 24-hr energy expenditure per rat increased with increase in wt of the total organism with a precipitous decline in total energy expenditure in the terminal stage of tumor growth. The average total 24-hr energy expenditure before transplant in 12 animals ranged from 39.8-50.5 Kcal with the mean activity compartment ranging from 21.2%-28.2% compared to a range of 23.6-60.4 Kcal and a mean activity compartment of 11.9%-25.6% at the end of the tumor growth period. A linear relationship existed between tumor energy cost estimated from the constant activity of the host and the estimate of metabolizing tumor size. This study showed no evidence of a consistent rise in resting metabolism during tumor growth.

- 704 ON THE ORIGIN OF EWING'S TUMOR. (E.) Kadin, M. E. (Stanford U. Sch. Med., Calif.) and K. G. Bensch. *Cancer* 27(2):257-273, 1971.

A specimen of Ewing's tumor, resected from the leg of a 10-yr-old boy, was examined electron microscopically and maintained in tissue culture. The tumor had infiltrating margins, and neoplastic cells could be found beneath and within the vascular endothelium. Under electron microscopy, a striking feature of the tumor was the presence of large amounts of glycogen in the tumor cells, together with scarcity of other cytoplasmic organelles. Cell membranes were partially or altogether absent near zones of necrosis. In culture, the tumor tissue showed the growth pattern of a malignant mesenchymal tumor; there was a gradation in cell shape from round to narrow and spindle-shaped. Elongate cells contained relatively little cytoplasmic glycogen compared to the more rounded cells. In some clones of cells growing for more than 3 wk, multiple prominent Golgi zones were found which were characteristic of developing myelocytes. Alkaline phosphatase activity was minimal in elongate cells and notable in rounded cells; acid phosphatase was demonstrable only in cells which had been in tissue culture for long periods. Tumor cells showed no esterase activity. The findings appear to suggest that Ewing's tumor is a neoplasm of myelogenous origin with a growth and proliferation pattern similar to plasma cell myeloma.

- 705 FIBROADENOMAS IN THE BREAST OF JUVENILES. (E.) Ashikari, R. (Mem. Hosp. Cancer Allied Dis., New York, N. Y.), J. H. Farrow and S. O'Hara. *Surg Gynec Obstet* 132(2):259-262, 1971.

The pathology of mammary fibroadenomas developing in adolescent girls was examined in 181 hospital cases. Of these tumors, 169 were classified as the adult type, and 12 as the juvenile type lesion. The patients ranged in age from 10-20 yr. Fibroadenomas in juveniles were usually solitary and larger than fibroadenomas of the adult type; the largest tumor observed measured 19 cm. Microscopically, numerous irregularly proliferating duct-like and tubular structures were seen in the tumors; the stroma were dense, and more cellular than in adult type fibroadenomas. Mucinous degeneration and osseous metaplasia were also uncommon. Juvenile type fibroadenomas were always benign.

- 706 A STUDY OF THE ENDOMETRIUM IN INTRAUTERINE CONTRACEPTIVE DEVICE USERS. (E.) Rimdusit, S. (Siriraj Hosp., Bangkok, Thailand), A. Koetsawang, S. Tanapongpipatana and D. Rajawat. *Med Ass Thailand* 53(12):843-847, 1970.

The endometria of 210 users of intrauterine contraceptive devices (IUD) were examined by biopsy to determine the prevalence of malignant or premalignant changes in the endometrial tissue of IUD users. The study population ranged in age from 17-46; their parity ranged from 1-9. Of the 210 women, 112 were symptom-

free and 98 were symptomatic; no malignancy was found. There were 9 cases of endometrial hyperplasia and 27 cases in which the endometrial pattern involved a proliferative or secretory condition with lymphocyte or polymorphonuclear leucocyte infiltration. Most of the patients with endometrial hyperplasia were under 30-yr-old.

- 1707 OSTEOSARCOMA DEVELOPING IN SOLITARY ENCHONDROMA OF THE TIBIA. (E.) Rockwell, M. A. (Coll. Med., U. Florida, Gainesville) and W. F. Enneking. *J Bone Joint Surg* 53(2):341-344, 1971.

SUBJECT INDEX

- 2-ACETYLAMINOFLUORENE
 - METABOLITE, BINDING, RAT LIVER, NUCLEIC ACIDS (1301)
 - MOUSE, BLADDER, EPITHELIUM (1300)
- ACHALASIA
 - CARCINOMA, ESOPHAGUS (1700)
- ACTINOMYCIN D
 - PUROMYCIN, LYMPHOCYTES, PHYTO-HEMAGGLUTININ (1678)
- ADENOCARCINOMA
 - IMMUNOSUPPRESSION, THYMECTOMY, RADIATION, MICE (1552)
- ADOLESCENCE
 - MAMMARY FIBROADENOMAS (1705)
- ADRENAL GLAND
 - ADRENOCORTICAL VIRILIZING CARCINOMA, STEROIDS (1642)
 - HISTOCHEMISTRY, WHOLE BODY IRRADIATION, RAT (1407)*
 - NEUROBLASTOMA, ANTIGENS, FETUS, (1577)
- AFLATOXIN
 - B1, CHICK LIVER, CARBOHYDRATE METABOLISM (1311)
 - B1, ENZYME HISTOCHEMISTRY, MUCOR HIEMALIS FUNGUS (1376)*
 - B1, LIVER MICROSOME, REPTILE, FOWL (1309)
 - B1, RAT LIVER, TRANSFORMATION, IN VITRO (1312)
 - B1, STRUCTURE-ACTIVITY RELATIONSHIP, TROUT (1308)
 - MYCOTOXINS, BLOOD MALIGNANCIES, LIVER CARCINOMA (1276)
 - P1, MONKEY, AFLATOXIN METABOLITE (1310)
- AGE
 - BENZO(A)PYRENE, ORGANOTROPY, HUMAN (1333)
 - FIRST PREGNANCY, MAMMARY CARCINOMA, WEIGHT (1618)
 - URETHAN, TUMOR INDUCTION, HAMSTERS 1361
- AMINO ACID
 - ALPHA-AMINOISOBUTYRIC ACID UPTAKE, IRRADIATED RAT LIVER (1386)
 - COMPOSITION, T-ANTIGEN, ADENOVIRUS TYPE 12, HAMSTER (1526)
- ANILINE
 - RAT CORPOREA LUTEA, STEROIDOGENESIS (1319)
- ANTIBODY
 - IMMUNOGLOBULIN PRODUCTION, MURINE PLASMACYTOMA (1546)
 - MONKEY KIDNEY, SV40, VIRUS REPLICATION (1495)
 - MULTIPLE MYELOMA, KEYHOLE LIMPET HEMOCYANIN (1576)
 - RESPONSE, GROSS LEUKEMIA VIRUS, LYMPHOMA (1520)
 - SV40, LABORATORY MONKEY HANDLERS (1524)
- ANTIGEN
 - CHICK-EMBRYO-LETHAL-ORPHAN VIRUS, CHICK KIDNEY CELLS (1417)
 - COMMON ANTIGENICITY, ANEMIA-INDUCING PLACENTAL SUBSTANCE, MUCOPROTEIN IN URINE OF CANCER PATIENTS (1575)
 - COMMON ANTIGENICITY, MAMMARY TUMOR VIRUS, MOUSE (1536)
 - COMPLEX, AVIARY SARCOMA, ROUS SARCOMA VIRUS (1527)
 - CROSS-REACTIVITY, MAREK'S DISEASE, EPSTEIN BARR VIRUS, HERPESVIRUS (1466)
 - FOCUS FORMATION, HUMAN SARCOMAS IN VITRO (1427)
 - GASTROINTESTINAL MALIGNANCIES, HUMAN FETAL GUT ANTIGEN (1566)
 - GROSS VIRUS, MURINE LEUKEMIA (1523)
 - GROUP-SPECIFIC, MURINE SARCOMA VIRUS (1476)
 - HEPATITIS-ASSOCIATED, FAMILIAL HEPATOMA (1712)*
 - LEUKEMIA, ASCITES TUMOR (1549)
 - LYMPHOBLASTOID CELLS, BURKITT'S LYMPHOMA, EPSTEIN BARR VIRUS (1532)
 - LYMPHOCYTES, MALIGNANT LYMPHOMA (1542)
 - MAREK'S DISEASE, HERPESVIRUS, PATHO-GENICITY (1467)
 - NEUROBLASTOMA, FETUS, ADRENALS (1577)

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain two-hundred abstracts and twenty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume IX covers the scientific literature published from July 1970 through June 1971. A cumulative subject and author index for Volume IX will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows:

Carcinogenesis Abstracts

23 DISEASES PREDISPOSING TO LYMPHOID MALIG-
NANCIES. (E.) Drake, B. J. (Northwestern
Med. Sch., Chicago, Ill.), W. A. Caro and S. M.
uefarb. *Cutis* 7(4):413-417, 1971.

herited diseases of immunologic deficiency asso-
ciated with lymphoma development include ataxia-
telangiectasia, Wiskott-Aldrich syndrome and Chediak-
Higashi syndrome. Ataxia-telangiectasia patients
are at an unusually high risk for developing lympho-
sarcoma, reticulum cell sarcoma and Hodgkin's disease,
perhaps reflecting lymphocyte incompetence involved
in this condition as well as humoral and cell-media-
ted immune deficiency. Lymphocyte depletion is also
a feature of the Wiskott-Aldrich syndrome, which pre-
disposes patients to lymphoma. Although humoral and
cellular immune responses in the Chediak-Higashi syn-
drome are normal, patients show an increased suscep-
tibility to lymphoma and viral infection. Among cy-
togenetic disorders predisposing to leukemia are in-
cluded Bloom's syndrome, Fanconi's anemia, Down's
syndrome and Klinefelter's syndrome; in Bloom's syn-
drome an apparent predisposition to malignancy has
been observed but not substantiated in detail. Among
the mastocytoses, urticaria pigmentosa is associated
with an increased risk of leukemia development, most
all leukemia being the predominant form. (16 refer-
ences)

24 CANCER AND DIABETES MELLITUS: A REVIEW
OF THE LITERATURE. (E.) Kessler, I. I.
Harvard Sch. Publ. Hlth., Boston, Mass.) *J Chron*
Dis 23(8):579-600, 1971.

Carbohydrate metabolism tests performed on patients
with cancer of various sites have shown that diabetes
is more common among cancer patients than among non-
cancer patients; the association between pancreatic
cancer and diabetes was found to be especially strik-
ing. Evidence for a similar correlation between can-
cer of the uterine endometrium and diabetes was con-
flicting. Most autopsy-based investigations have in-
dicated that there is a negative correlation between
cancer and diabetes; however, autopsy surveys may be
subject to inherent biases which conceal positive
relations between cancer death and diabetes inci-
dence. Statistical studies of cancer risk among dia-
betic patients have had equivocal results; these stud-
ies have, however, clearly shown that there is a high-
er than normal risk of developing pancreatic cancer
among diabetics. (128 references)

25 SENESCENCE AND JUVENILE FACTORS IN THE
NEOPLASTIC CELL. (It.) Dianzani, M. U.
Inst. General Path. U. Torino, Italy). *Giorn*
Patol 18(4):245-279, 1970.

In a review of the literature of the relationship
between aging and carcinogenesis, note was taken
of the fact that experimentally induced tumors oc-
cur mostly in young animals, while spontaneous
tumors occur mostly in animals of advanced age.
Normal cells and cancer cells are not similar bio-
chemically or morphologically; however aging and

the process of carcinogenesis may act upon elements
common to aged cells and cancer cells. The theory
that aging is a result of lifelong exposure to
irradiation may provide insight into the relation-
ship between aging and carcinogenesis, for it is
known that cancer can result from exposure to ir-
radiation. (185 references)

1726 MICROORGANISMS ASSOCIATED WITH MALIGNANCY.
(E.) Pease, P. (Dept. Bacteriol., U. Birmingham,
England). *Ann NY Acad Sci* 174(2):782-785, 1970.

A group of related bacteria have been found in
association with malignancies in the newt and
may be associated with human tumors. These bacteria
are gram-positive, weakly acid-fast, and vary in
morphology from small spheres to long rods. There
is evidence which suggests the possibility that
bacteria of this type in the L-form resemble the
Rous sarcoma virus and may even be identical with
this carcinogenic virus. Bacteria of the group
in question are widespread in nonmalignant
patients as well as in patients with cancer; it is
suggested that, if the microbes have a causal connec-
tion with cancer, their efficacy may depend on unus-
ually large quantities of bacteria accumulating in
a single patient. There is reason to believe that
the group of bacteria discussed are members of the
Mycococcus bacteria class. Other bacteria found in
association with malignancy are *Agrobacter* and
Listeria group organisms. (29 references)

1727 PARASITISM AND CANCER. (Fr.) Juminer, B.
(Inst. Pasteur, Tunis). *Arch Inst Pasteur*
Tunis 47(3):211-227, 1970.

A review of the medical literature does not support
either the etiological or pathogenic relationship
of cancer to parasitism. Although cestodes in ani-
mals and trematodes in humans have been found in
some organs together with cancer, and although bil-
harziasis and cancer of the bladder have been
found simultaneously, the arguments against there
being a causal relationship are strong. There is
some indication that toxoplasmosis may be linked
to primary cancer of the nervous system, but the
evidence for this is still meager. The connection
between the pathogenesis of cancer and the parasitic
etiology is founded on a predisposition for the ter-
rain to favor the development of both diseases, a
specific role of certain metabolites either produced
or induced by the parasite, or a true carcinogenic
power organically related to the parasite. However,
these connections are derived for the most part from
epidemiological data and no valid experimental evi-
dence exists that this relationship is causal. (47

1728 CELLULAR COMMUNICATION, CONTACT INHIBITION,
CELL CLOCKS AND CANCER: THE IMPACT OF THE
WORK AND IDEAS OF W. R. LOEWENSTEIN. (E.) Burton,
A. C. (Dept. Biophys., U. Western Ontario, London,
Canada). *Perspective Biol Med* 14(2):301-318, 1971.

Theories of cellular interaction for normal and malignant cell proliferation are discussed. Loewenstein's discovery that normal liver cells exchange substances of high molecular weight while cancer cells have little intercommunication prompted the hypothesis that all living cells retain the ability to divide, and that living cells divide or remain in interphase as a result of intercellular factors. Such intercellular factors, which promote cellular intercommunication, may be mediated by the electrical resistance between neighboring and distant cells. This suggests that malignant cells differ from normal cells in that the former do not freely communicate with other cells in contact with them. The breakdown in intercellular communication, according to this theory, triggers malignant proliferation. In normal cell systems, contact inhibition operates by providing individual cells with "information" as to the optimal size of the cell colony, restraining the cell from division. For contact inhibition to operate, one substance within the cell must have a concentration gradient which regulates cell division and which is altered by neighboring cells. Agents which reduce communication between cells or which cause cells to divide synchronously would reduce contact inhibition or preclude it altogether, leading to malignant cell proliferation. Radiation in this theory might be considered carcinogenic because cells recovering from radiation damage become synchronous. An upset in the regular rhythm or cycle of biochemical events in cells might also promote malignant proliferation, even in instances when cells are not synchronous and intercellular communication is satisfactory. (22 references)

- 1729 A NEW CONCEPTUAL FRAMEWORK FOR SARCOMA.
(E.) Siegler, R. (Boston U. Med. Sch.,
Mass.) *Bibl Haemat* 36:257-260, 1970.

Spontaneous reticulum cell sarcomas of mice and Moloney virus-induced mouse sarcomas were studied in an attempt to arrive at a comprehensive theory of pathogenesis for sarcomas as opposed to carcinomas. While carcinomas appear to grow by clonal proliferation of a population of malignant cells originating from a single mutant cell, sarcomas do not grow by clonal proliferation of daughter cells. Both sarcoma systems studied appeared to grow by the continuous recruitment by the tumor cells of adjoining normal tissue. Animals dying of sarcomas may die because they are unable to check the spread of malignant tumors to normal tissue, and not because they are preyed upon by a genetically-determined population of malignant cells as in carcinoma. Whether a sarcoma induced by virus ultimately kills the affected animal appears to depend on whether or not the spread of the sarcoma has impinged upon vital organs; hence, the presence of an effective immune response to impede or halt the spread of the sarcomas in affected animals was crucial for their survival. Proliferative lesions of the mesenchyme are probably a normal physiologic response designed to repair tissue injury; when host immune mechanisms are inadequate to check the repair proliferation of cells, the lesion produced by this proliferation will be of the type called "sarcoma". (2 references)

- 1730 THE PHILADELPHIA CHROMOSOME. (Ger.)
Hossfeld, D. K. (Roswell Park Mem. Inst.,
Buffalo, N. Y.) and A. A. Sandberg. *Klin Wschr*
48(24):1431-1441, 1970.

The presence or absence of the Philadelphia chromosome (Ph¹) in karyotypes of patients with chronic myelocytic leukemia (CML) divides these patients into those with good prognoses and those with poor prognoses, resp. Ph¹ positive males with CML who lack a Y chromosome in leukemic cells have especially favorable prognoses. Although it is most regularly associated with CML, the Ph¹ chromosome has also been found in patients with acute myeloblastic leukemia, polycythemia, myeloid metaplasia and thrombocytopenia. Although chromosomal aberrations other than Ph¹ chromosome occur in more than 65% of CML patients, it has not been shown that these anomalies cause the blastic transformation associated with CML. Ph¹ chromosome-like deletions have been produced by exposure to ionizing radiation. There is some reason to believe that the Ph¹ chromosome may originate in a differentiated cell type, rather than in an altered stem cell. (174 references)

- 1731 ULTRASTRUCTURAL ALTERATION OF THE MITOCHONDRIAL ELECTRON TRANSPORT CHAIN INVOLVING ELECTRON LEAK: POSSIBLE BASIS OF "RESPIRATORY IMPAIRMENT" IN CERTAIN TUMORS. (E.) Arcos, J. C. (U.S. Publ. Hlth. Serv. Hosp., New Orleans, La.). *J Theor Biol* 30(3):533-543, 1971.

The decrease in the high amplitude swelling and contraction of tumor mitochondria is hypothesized to be due to an absent or severely altered mechanochemical effector system. Alterations in this system which is normally linked to the electron transport chain are also considered to be associated with the changes in fatty acid, phospholipid and cholesterol metabolism known to occur in tumor tissues. The altered cellular lipid pattern may result in lesions of tumor mitochondria such that leakage of electrons from the chain may occur. Substrate oxidation may then proceed as normally, but a fraction of the electrons may not reach the terminal acceptor, oxygen, resulting in a decrease of the respiratory rate. (69 references)

- 1732 KINETICS OF THE PROLIFERATION OF CANCER CELLS. (Fr.) Stryckmans, P. (Jules Bordet Inst. Tumor Ctr., Free U. Brussels, Belgium). *Acta Chir Belg* (Suppl. 1):7-17, 1971.

The growth of a tumor represents the breakdown of the state of equilibrium of normal tissues, and involves inequality of cell production and cell loss. The growth of tumors has been measured by its volume doubling time, implying an exponential growth. This concept was disputed by Laird who studied the normal growth of a guinea-pig from 40 days before its birth to 140 days after and described this growth by an asymmetrical sigmoid curve (Gompertz equation), showing an exponential diminution in the rate of growth. Tumors from 3 species of animals

(rat, mouse, rabbit) were shown to develop along this type of curve. The cellular loss may be due to different factors (cellular death; maturation in different compartment, desquamation or emigration) and should be determined. Observations made on the growth of metastases of human tumors are only valid for that metastasis; others in the same patient may have a different rate of growth. This indicates that the total population of tumor cells in the organism may be extremely heterogeneous and that the parameters of production may vary from one location to another, as would the chemotherapeutic effect. (21 references)

733 REFLECTIONS ON LATENT VIRUSES - A NEW DEFINITION OF AN INFECTIOUS AGENT. (E.) Hirschman, S. Z. (Mount Sinai Sch. Med., City U. New York, N. Y.). *Mt Sinai J Med* 38(2):257-266, 1971.

Recent experimental work on latent virus infection has been reviewed, and hypotheses accounting for the activation of a latent virus infection and subsequent malignant progression were aired. It has been shown that various RNA viruses, including murine leukemia and sarcoma viruses, may be present in a latent state in animal tissues, and that virus replication may be triggered by serial passage of the host cells or by irradiation. The discovery of an RNA-dependent DNA polymerase suggests a mechanism for the beginning of overt infection and viral replication of latent viruses. Viral RNA may synthesize DNA in the host cells; more viral DNA may then be produced by means of a DNA-dependent DNA polymerase, and the new DNA would code for the production of viral RNA, initiating viral replication. Such a hypothesis would account for the stimulation of DNA synthesis by RNA viruses, the spontaneous appearance of RNA leukemia virus in mouse cells, and the induction of leukemia by X-irradiation. Models for viral replication which would account for the viral latent state were also discussed. A virus may consist in some cases of protein which can induce normally inactive or "switched off" host cell DNA to reproduce the same proteins (the "self-induction" theory). Possible candidates for such a proteinaceous virus might be the Australia antigen and certain so-called "slow-growing" viruses. (38 references)

734 THE VIRAL THEORY OF CANCER AND EXPERIMENTAL ANTICANCER IMMUNITY. (Fr.) Gross, L. (VA Hosp, Bronx, N. Y.). *Bull Inst Pasteur* 69(2):193-208, 1971.

Experiments supporting the viral theory of cancer are reviewed, including among others: viral induction of leukemia and lymphosarcoma in mice; erythroblastosis and myeloblastosis in birds; visceral lymphomatosis in chicks (transmissible via the egg or by the airborne route); lymphosarcoma and fibrosarcoma in cats. The viral characteristics have been verified in most cases by electron microscopy. Potential oncogenicity of latent viral material has been demonstrated in anti-blepharitis vaccines from monkey kidney cell cultures which contain traces of SV40 virus contaminant capable of inducing sarcoma in newborn hamsters.

Latent human adenovirus has been shown to produce sarcoma in rats, mice and newborn hamsters. Although proof is lacking for viral transmission of cancer in man, it is reasonable, from evidence in animals, to formulate an hypothesis whereby the activation by external (chemical compounds, radioactivity, etc.) or internal (hormones, abnormal metabolites, etc.) stimuli of latent oncogenic viruses in one organism produces active oncogenesis. Immunization against experimentally induced cancer in animals by injection of minute amounts of neoplastic cells has been demonstrated. (53 references)

1735 STRAIN MC29, AN AVIAN LEUKOSIS VIRUS OF UNIQUE PROPERTIES. (E.) Langlois, A. J. (Duke U. Med. Ctr., Durham, N. C.), D. Beard and J. W. Beard. *Bibl Haemat* 36:96-105, 1970.

An avian leukosis virus, strain MC29, having properties distinguishing it from other leukosis viruses, is described. MC29 causes principally myeloid and renal tumors; mesothelial growths and hepatocytomas have also been associated with MC29 virus. Chick embryo cells in culture respond rapidly to infection with MC29, as measured by release of virus. Cells transformed by MC29 *in vitro* alter in morphology soon after infection. MC29 is antigenically similar to other leukosis viruses including Rous sarcoma virus and strain BAI. (50 references)

1736 MYELOMA PROTEINS (M-COMPONENTS) WITH ANTIBODY-LIKE ACTIVITY. (E.) Potter, M. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *New Eng J Med* 284(15):831-838, 1971.

Five antigens for which multiple "M-components" have been found were discussed; M-components were defined as antigen-binding homogeneous immunoglobulins produced by benign or malignant monoclonal disorders. Among M-components with antibody-like activity, the anti-IgG or rheumatoid factors have been found in 2-20% of normal persons and in 75-100% of patients with rheumatoid arthritis. The highest titers of rheumatoid factors have been found in patients with malignant monoclonal disorders. The chemical nature of the rheumatoid factor has yet to be precisely described. Antistreptolysin O has been found in the sera of patients with multiple myeloma and in patients with benign monoclonal disorder. Cold agglutinins, including anti-I and the I antigen system, may arise in the body from an exogenous source. M-components having anti-lipoprotein have been described in patients with multiple myeloma, hyperlipidemia and xanthomatosis. Plasma cell tumors induced in mice produced antipolysaccharide and antiphosphoryl choline IgA myeloma proteins. The antigens eliciting the M-component reaction include bacteria in the gastrointestinal tract. M-components which bind antigen may arise from the stimulation to malignant growth by antigens of a clone of cells, or as a result of an abnormal adjuvant effect stimulating the immune system. (53 references)

- 1737 IMMUNOCYTOMA O' MICE AN' MEN. (E.) Hobbs, J. R. (Westminster Med. Sch., London, England). *Brit Med J* 2(5753):67-72, 1971.

The growth of a monoclonal of cells (an immunocytoma) is indicated when narrow bands which can be identified as being due to a single type of immunoglobulin are formed on electrophoresis; the growth of such cells is monitored by measuring paraprotein levels and looking for evidence of dedifferentiation. For an ascitic form of plasmacytoma, estimates of the actual total number of plasmacytoma cells in a mouse were obtained by isotope dilution and a positive correlation with the serum level of paraprotein was demonstrated. It was further shown that such tumor growth was exponential in mice. For human patients screened for the M.R.C. Myeloma Trials, the rise of serum IgG or IgA paraprotein levels, or the 24-hr urinary output of Bence Jones protein was also found to be exponential. Studies of plasmacytoma in mice and men indicate that it takes some 21 yr from the time a single plasma cell precursor is transformed for clinical IgA myelomatosis to become apparent. Bence Jones proteins were found to be free monoclonal light chains resulting from an imbalance in heavy and light chain synthesis by malignant myeloma cells, presumably through dedifferentiation. Four features useful in predicting a benign or malignant immunocytoma were presented. The use of high dosages (1 mg/kg body wt) of drugs such as melphalan and cyclophosphamide for short periods was recommended in treating myelomatosis. (35 references)

- 1738 REVIEW OF THE PRESENT STATUS OF RESEARCH IN TUMOR SPECIFIC TRANSPLANTATION ANTIGENS IN HUMAN LEUKEMIA. (Ger.) Zintl, F. (U. Child Clin., Jussuf Ibrahim, Jena, Germany) and W. Plenert. *Folia Haemat* 95(1):1-20, 1971.

A review of tumor induction in mice by means of viral carcinogens is presented, and some findings in man of virus-like particles in lymph nodes, bone marrow and blood plasma concentrates from acute lymphatic leukemias and chronic myeloses are reported. Mixed virus-like particles have also been found in infectious mononucleosis. Immunological studies relating lymphatic, myeloid, reticular and erythroblastic leukemias are described. Human leukemia and lymphomas in connection with tumor specific transplantation antigens (TSTA) are reviewed, including the isoantigens of leukemia cells, Burkitt's lymphoma, Epstein-Barr virus, cellular defense mechanisms against TSTA of human leukemia (by *in vivo* and *in vitro* experiments) as well as humoral defense mechanisms, and heterologous, homologous and autologous antisera against leukemic cells. Therapy is discussed with special attention to immunostimulation in contrast to immunosuppression. (124 references)

- 1739 IMMUNOLOGICAL STUDIES ON BURKITT'S LYMPHOMA. (E.) Klein, G. (Karolinska Inst., Stockholm, Sweden). *Postgrad Med J* 47(545):141-155, 1971.

Recent developments concerning the antigenic properties of Burkitt's lymphoma are reviewed and discussed. When fresh Burkitt's lymphoma biopsy cells were exposed to sera from patients with Burkitt's lymphoma and other malignancies and to sera from patients with nonneoplastic disease, indirect membrane immunofluorescence tests indicated that the Burkitt's lymphoma sera contained an attached immunoglobulin which was not found in sera from other patients. The degree of immunoglobulin coating on the surface of the biopsy cells was found to vary. The immunoglobulin appeared to be IgM and/or IgG. The membrane antigen found on Burkitt's lymphoma cells was thought to be determined by the genome of the Epstein-Barr virus which is found in some Burkitt's lymphoma cells in culture. Recent evidence has suggested that the antigen may represent a viral envelope component. Serological studies of various populations relative to Burkitt's lymphoma have indicated that serological anti-Epstein-Barr virus activity is widespread in all human communities. The disease-related distribution of anti-virus antibody patterns is discussed, and it was noted that there is preliminary evidence that the antibodies against the soluble Epstein-Barr virus antigens appear during tumor growth and decline in number during tumor regression. It was not certain whether the virus-associated membrane antigens are essential for the neoplastic development of cells in Burkitt's lymphoma. (111 references)

- 1740 INTERACTION OF HOST AND CANCER: THE POTENTIAL ANTIGENICITY OF CANCER CELLS, THE DEFENSE MECHANISMS OF CANCER PATIENTS, AND THE INFLUENCE OF ENDOCRINE GLANDS AND AGING ON CANCER. (E.) Mulligan, R. M. (U. Colorado Sch. Med., Denver). *Exp Med Surg* 28(1):1-17, 1970.

Electron microscopic studies reveal a proportionate host response to the complexity of structures within cancerous cells indicative of protein elaboration, delayed hypersensitivity and antibody production in patients with non-hematopoietic cancer. Patients with lymphopoietic cancer display decreased resistance to infection and interference with synthesis of globulins of 7S and 19S types. Increased nucleic acid synthesis, heightened activity of melanoblasts, decreased differentiation of epithelial and lymphopoietic cells relative to the alteration in somatotrophin, melanotrophin and thyroglobulin production, delayed or declining immune competence of thymus and lymphoid tissue in childhood and adult life, resp., antimetabolic effects of hydrocortisone, and decreased secretion of sex hormones all favor the induction of carcinoma. (40 references)

- 1741 THE HEALTH MENACE OF TOBACCO. Ochsner, A. (Ochsner Clin., New Orleans, La). *Amer Sci* 59(2):246-252, 1971.

The epidemiological evidence establishing a causal connection between tobacco use and cancer is rehearsed. The increase in mortality from lung cancer in the United States between 1930 (2,500 deaths) and 1964

43,100 deaths) appears to be related to the fact that cigarette smoking did not become a widespread practice in the United States until the time of the First World War. Statistics from Iceland show that lung cancer mortality began to increase in that country around 1955, and that cigarette smoking became prevalent in Iceland during the Second World War. Adenocarcinoma of the lungs does not appear to be associated with smoking. It also appears that the chance of developing cancer decreases among those who stop smoking, the decrease accompanying the time elapsing since cessation of smoking. Other cancers caused by smoking include laryngeal cancer, which is also on the rise in the United States, lip, tongue and oral cancer, esophageal cancer and cancer of the urinary bladder. Bladder cancer is thought to be caused by cigarette smoke interfering with metabolism in such a way as to promote the excretion of carcinogens in the urine. (50 references)

1742 CONTRACEPTION AND CANCEROGENIC RISKS. (Fr.) Cappelaere, P. (no affil). *Lille Med 16 Special*:45-51, 1971.

From experimental findings in animals and from cytological evidence, the use of intrauterine devices for contraception have led to either an inflammatory process close to the uterus which can disappear after removal of the device, the development of an epidermoid metaplasia followed by a squamous epithelioma, or to a persistent chronic inflammatory lesion which favored the development of an endometrial adenocarcinoma. However, none of these manifestations were found in humans including the intermediary stage of epidermoid metaplasia. The use of hormonal contraception, as well as hormone therapy, is not considered as favoring the development of cervico-uterine cancer, and neither uterine (or endometrial) nor mammary cancers have found clinical confirmation attributable to hormonal contraceptives. (65 references)

1743 STEROID CONTRACEPTIVES. (E.) Vande Wiele, R. L. (Coll. Phys. Surg., Columbia U., New York, N. Y.). *Gynec Invest 1*(suppl.):55-66, 1970.

The chemistry and physiological modes of action of steroid contraceptives were described in a brief descriptive review, and the changes in certain body systems induced by these agents were considered. Functions which are influenced to one degree or another by ingestion of oral contraceptives include ovarian function, carbohydrate and lipid metabolism, protein metabolism, liver function and circulation. Statistics were produced indicating that users of steroid contraceptives are at a higher risk than nonusers of developing thromboembolic diseases. Despite recent studies which suggest that women taking oral contraceptives have an increased prevalence of abnormal Papanicolaou smears and possibly of carcinoma *in situ* of the cervix, there was thought to be no reason to believe that use of steroid contraceptives affects the incidence of cancer either positively or negatively. 1744 AFLATOXINS. (E.) Wogan, G. N. (Dept. Nutr. Food Sci., Massachusetts Inst. Tech., Cambridge) and R. S. Pong. *Ann NY Acad Sci 174*(2): 623-635, 1970.

The biogenesis, chemical nature, and the biological and chemical effects of aflatoxins is summarized. Aflatoxin-producing fungi are widely dispersed in air and soil, are capable of growth on a wide variety of natural substrates, chiefly grains, exhibit a strong fluorescence in ultraviolet light, and can readily be separated by thin-layer chromatography in various fractions. Their relative solubility in polar organic solvents and sparing solubility in water has been utilized in the development of physicochemical assays for their detection and quantitation in foods. *In vivo* studies have revealed a relationship between chemical structure and acute lethality with B₁ being most toxic, followed by G₁, B₂, and G₂ in decreasing potency; *in vitro* studies have shown the aflatoxins to be capable of inducing mitotic inhibition as well as chromosome aberrations. The carcinogenic capacity of aflatoxin has been demonstrated in rats, ducks, trout and ferrets, and has been shown to be enhanced by protein depletion and liver cirrhosis in the rat, in which it is inhibited by hypophysectomy. Aflatoxin inhibition of DNA synthesis has been seen subsequent to partial hepatectomy, and changes in hepatocyte nuclear fine structures have revealed that the agent affects RNA metabolism in rat liver. Their hepatotoxic and carcinogenic properties in animals give particular importance to questions concerning their possible public health significance. (80 references)

1745 BIOPHYSICS (4-NITROQUINOLINE-1-OXIDE). (E.) Nagata, C. *Rec Results Cancer Res 34*:17-31, 1971.

Based upon the electronic structural features of 4-nitroquinoline-1-oxide, it was predicted that a charge transfer complex would form between this molecule and the DNA base adenine. The quantity of charge transferred to 4-nitroquinoline-1-oxide (4-NQO) and its related compounds correlated well with their carcinogenicity. Physical binding of 4-NQO to DNA was proved *in vitro*. The orientation within DNA was parallel to the base planes, and the affinity for purine bases was stronger than that for pyrimidine ones. Maximum binding occurred at ratios of DNA to 4-NQO greater than 7 to 1. *In vitro* experiments indicated that 4-NQO and 4-hydroxyaminoquinoline-1-oxide (4-HAQ) bind covalently to the bases of nucleic acids, whereas no such binding was shown for non-carcinogenic quinoline-1-oxides. The amount of 4-NQO bound is about 1 molecule/10⁴ nucleotides of DNA, whereas for 4-HAQ there is approximately 0.5-1.5 molecule/1000 nucleotides of DNA. Binding to SH compounds such as cysteine and glutathione was demonstrated for 4-NQO and a charge transfer complex with protein or aromatic amino acids was also shown. UV irradiation of 4-NQO in the solid state or in organic solvents resulted in free radical formation. ESR signals in dioxane, hexane and benzene differed from each other, indicating that different kinds of

free radicals were formed according to the solvents used. In hexane and benzene the unpaired electron is localized on the nitro-group nitrogen atom whereas in dioxane it is delocalized. Without photoirradiation, 4-HAQ was found to convert oxidatively to a free radical, the structure of which was determined with the aid of ^{15}N and/or D replacement method. Free radical formation is considered to have some influence on the oxidation-reduction processes of biological systems and play an important role in the carcinogenic processes of these compounds. The photodynamic activity of 4-NQO on *Paramecium caudatum* was found and a relationship was observed between photodynamic activities and carcinogenicities of quinoline-1-oxides. This relationship does not hold for 4-HAQ and its derivatives. Photoirradiation of 4-NQO in the presence of nucleic acids, resulted in the destruction of the guanine moiety. (References)

- 1746 CARCINOGENICITY (OF 4-NITROQUINOLINE-1-OXIDE). (E.) Endo, H. (no affil). *Rec Results Cancer Res* 34:32-52, 1971.

Experimental carcinogenesis induced by 4-nitroquinoline-1-oxide in varying doses and methods of administration and in varying animal systems was reviewed. More than 65 experiments in which 4-nitroquinoline-1-oxide or one of its derivatives were given to rodents (including mice, rats, hamsters and guinea pigs) were tabulated. Topical painting of the carcinogen appeared in general to produce a higher incidence of tumors in recipients than did injection. Common types of tumors induced by 4-nitroquinoline-1-oxide included squamous cell carcinomas and papillomas; lymphatic tumors and proliferative conditions of the blood were produced less commonly. In addition to producing tumors when administered to living animals, it was also noted that 4-nitroquinoline-1-oxide induces cell transformation *in vitro*. (References).

- 1747 DANGER THROUGH CARCINOGENIC SUBSTANCES IN THE ENVIRONMENT. (Ger.) Gräf, W. (Inst. Hyg., U. Erlangen-Nuremberg, Germany). *Oeff Gesundheitswesen* 33(3):121-133, 1971.

Over 600 substances suspected of being carcinogenic are classified under chemical carcinogens: polycyclic aromatic hydrocarbons, aromatic amines, alkylating agents, nitrosamines, urethane, inorganic chemical poisons, high polymers, natural carcinogens, and cocarcinogens. The occurrence of these substances in our environment may be attributed to substances used in industry, air and water pollution, and naturally occurring substances in plant life. The carcinogenic properties of mycotoxin are described with special reference to the damage such fungi can cause when ingested in animal food mixtures. The nitrites may be used as preservatives for meat or vegetables and may also be found in the intestinal tract through bacterial reduction of nitrates in drinking water. Secondary amines may be produced in cooking or be traced to fish meal used in animal food. The polycyclic aromatic hydrocarbons are a product of our civiliza-

tion and include components of combustion and exhausts and smoke. In addition, these agents are found in nature, and the natural occurrence of benzo(a)pyrene and its effects on men and animals are reviewed (21 references)

- 1748 LUNG TUMORS OF PRIMATES AND RODENTS. (E.) Schepers, G. W. H. (no affil). *Indust Med Surg* 40(1):48-53, 1971.

In the first article in a 3-part series, a survey of 330 cases of human lung cancer observed over a 30-year period was reviewed; most of the cases were associated with exposure to some industrial carcinogen. In addition, lung tumors induced in animal by exposure to industrially significant substances were described. Proven industrial carcinogens included asbestos, nickel, soot, and chromium, and suspected carcinogens included beryllium, engine exhaust, tar fumes and mustard gas. High-risk industries included asbestos mining and manufacturing (prevalences of 32.7 and 51.3 per thousand, resp.), coal mining, gold mining, hematite mining, foundry work and chemical manufacturing. In a total of 130 experiments on guinea pigs, rats, swine, rabbits and cats, potentially carcinogenic chemicals encountered in industry were administered by tracheal injections. Malignant or premalignant changes in pulmonary tissues were induced in animal by beryllium, cadmium, diatomite, and silica, among other agents. (no references)

- 1749 LUNG TUMORS OF PRIMATES AND RODENTS: PART II. (E.) Schepers, G. W. H. *Indust Med Surg* 40(2):23-31, 1971.

Experiments were described in which monkeys and rodents inhaled putatively carcinogenic agents with which industrial workers might come in contact; the carcinogenicity of these agents for the animal lung included rabbits, guinea pigs, hamsters and rats. Only 6% of animals exposed to aluminum aerosols developed alveolar epithelialization and none developed pulmonary tumors. Quartz dust aerosols produced pulmonary lesions in 84% of animals, but produced alveolar epithelialization in only 2.3%. Two animals in the quartz aerosol group developed squamous carcinoma. Submicron amorphous silica compounds were less pathogenic than quartz dust; 67% of animals exposed to these particles developed lesions. Fibrous siliceous aerosols were less pathogenic than crystalline-free silica or submicron amorphous silica aerosols. 42% of the animals developed aerosols in this experimental group. Inhalation of beryllium salts produced lesions in 43% of the animals, alveolar epithelialization in 43% of the animals and lung tumors in 10% of the animals. Also tested were "miscellaneous aerosols", including oil smoke, chalcedony, diatomite, mineral oil, iron chloride and hematite. Lung tumors were seen in less than 0.3% of animals exposed to miscellaneous aerosols. Beryllium aerosol-induced tumors were readily transplanted to other animals through 5 generations of the same species. (no references)

(1750-1760)

- 1750 LUNG TUMORS OF PRIMATES AND RODENTS: PART III. (E.) Schepers, G. W. H. (no affil) *Industr Med Surg* 40(3):8-26, 1971.

The morphology of lung tumors induced in animals by administration of a wide variety of substances potentially dangerous to industrial workers was described. Among so-called "adenomatoid" carcinomata, the most malignant was the acinoid type, which metastasized frequently to the kidney. Other types of adenomatoid tumors were the papilligeroid, circinoid and mucigeroid; these types of tumor were composed primarily of cuboidal cells, columnar cells and goblet cells, respectively. Adenomatoid carcinomas were often induced in rats by inhalation of beryllium aerosols. Epidermoid pulmonary tumors were also seen; some were designated desquamative and some multilayered. Mesotheloid and lymphomatoid tumors were also seen. Among preneoplastic conditions observed in the lung tissue of animals exposed to carcinogens were alveolar epithelialization, bronchiolar epithelial plaque metaplasia, granulomatosis, lymphoid hyperplasia and pleural plaque formation. Whereas no clear morphological differences existed between benign and malignant animal lung tumors, it was noted that human tumors usually allow malignant-benign classification. A second major difference between human and animal tumors was the paucity of mesodermoid lesions in animals. Finally, while human tumors were known to arise frequently in the bronchi, animal lung tumors were found to originate more often in the lung parenchyma. (no references)

- 1761 INDUCTION OF LUNG ADENOMAS BY CHRONIC INHALATION OF BIS(CHLOROMETHYL) ETHER.
(E.) Leong, B. K. J. (Biochem. Res. Lab., Dow Chem. Co., Midland, Mich.), H. N. Macfarland and H. W. Reese, Jr. *Arch Environ Health* 22(6):663-666, 1971.

Male mice of the A/Heston strain were exposed for 82 and 101 days to bis(chloromethyl) ether (B-CME) or chloromethyl methyl ether (CMME), resp.; B-CME and CMME were introduced to the rats via an aerosol containing B-CME in concentrations of 1 ppm and CMME in concentrations of 2 ppm. Control rats were exposed to untreated air or to an urethan aerosol (138 ppm) for 130 days. The incidence of lung adenomas in the B-CME and CMME groups was 55 and 50% resp., and the average number of tumors per tumor-bearing animal in these 2 groups was 5.2 and 3.1, resp. The incidence of adenomas in the urethan group was 94% vs 41% for untreated controls, and the number of tumors per tumor-bearing animal in the urethan group was 57.5 vs 2.2 in untreated controls. B-CME caused loss of body weight and respiratory distress, but CMME caused no adverse effects. CMME and B-CME were thought to be potentially dangerous agents for industrial workers.

- 1762 MECHANISM OF CARCINOGENESIS WITH 1-ARYL-3,3-DIALKYL-TRIAZENES: III. *IN VIVO* METHYLATION OF RNA AND DNA WITH 1-PHENYL-3,3-[¹⁴C]-DIMETHYLTRIAZENE. (E.) Krüger, F. W. (German Cancer Res. Ctr., Heidelberg), R. Preussman and N. Niepelt. *Biochem Pharmacol* 20(3):529-533, 1971.

Thirty-four male Sprague-Dawley rats were injected i.p. with 0.1 ml/100 g body wt of 1-phenyl-3,3-¹⁴C dimethyltriazene and were killed 9.5 hr after treatment; RNA and DNA were prepared from the pooled organs. 7-Methylguanine was formed in the RNA of all tissues investigated and was also found to be present in the DNA of the liver. These results show that the carcinogen is metabolized in mammals to form an alkylating agent.

- 1763 POTENTIALLY CARCINOGENIC CYCLOPENTA[a]PHENANTHRENES: V. SYNTHESIS OF 15,16-DIHYDRO-7-METHYLCYCLOPENTA[a]PHENANTHREN-17-ONE. (E.) Coombs, M. M. (Imp. Cancer Res. Fund, London, England) and S. B. Jaitly. *J Chem Soc* 1971(2): 230-234, 1971.

Treatment of a 2-acetyl-3-methylnaphthalene furfurylidene derivative with acid was used to prepare 7-[2-(3-methylnaphthyl)]-4,7-dioxoheptanoic acid which was then treated with base; this treatment produced a high yield of a cyclopentenone which absorbed at 259 nm and readily underwent cyclization when boiled with acetic anhydride to give a high yield of 11-acetoxy-15,16-dihydro-7-methylcyclopenta[a]phenanthren-17-one. The parent phenol was prepared from the compound and reduced with sodium in liquid ammonia-tetrahydrofuran to furnish the required 15,16-dihydro-7-methylcyclopenta[a]phenanthren-17-one in 43% yield. The ultraviolet absorption and n.m.r. spectra were compatible with the assigned structure of the product.

- 1764 THE ONCOGENICITY OF N-7-HYDROXYLATED PURINE DERIVATIVES: 7-HYDROXYTHEOPHYLLINE. (Ger.) Guttner, J. (Inst. Microbiol. Exp. Ther., German Acad. Sci., Jena), M. Horn and W. Jungstand. *Arzneimittelforschung* 21(3):356-358, 1971.

Male and female 6-7 wk-old AB/J inbred mice were injected s.c. at 1-wk intervals for 25 wk with 0.7 mg and 1.4 mg of 7-hydroxytheophylline in normal saline and were observed thereafter up to 2 years. Since no dosage-effect relationship was apparent, results from both dose levels were combined. Autopsy findings and histological examinations disclosed that treatment with 7-hydroxytheophylline resulted in approximately 40% more cases of amyloidosis in both sexes than in control animals. No significant difference in mortality was found between controls and treated animals in reticulosarcoma and lung adenoma occurrence. Although no specific carcinogenic effect of 7-hydroxytheophylline could be demonstrated statistically, administration of the agent resulted in a shorter induction time for reticulosarcomas and lung adenomas in females as well as an increased incidence of these tumors in the second half of the animals' life span. This result is in agreement with the carcinogenic effect of this substance described in a previous report on sebaceous gland atrophy tests.

- 1765 CARCINOGENIC EFFECTS OF CYCASIN IN SYRIAN GOLDEN HAMSTERS AND THE TRANSPLANTABILITY OF INDUCED TUMORS. (E.) Hirono, I. (Gifu U. Sch. Med., Japan), K. Hayashi, H. Mori and T. Miwa. *Cancer Res* 31(3):283-287, 1971.

Newborn hamsters given a single s.c. injection of 0.2-0.6 mg cycasin/g body wt developed liver cell adenomas in 5.0% of cases, hepatocellular carcinomas in 8-9% of cases, and intrahepatic bile duct carcinoma in 8-14% of cases. Adult hamsters given a single intragastric dose of 0.15 or 0.1 mg cycasin/g body wt by stomach tube developed liver cell adenomas in 4-5% of cases, no hepatocellular carcinomas, and intrahepatic bile duct carcinomas in 11-22% of cases. Adult hamsters given 2, 3 and 4 administrations of 0.1 mg cycasin/g body wt at 1 month intervals developed liver cell adenomas in 11% of cases (56% of the hamsters given 4 doses of cycasin died within 10-60 days), no hepatocellular carcinomas, and intrahepatic bile duct carcinomas in 9-17% of cases. Eight liver tumors induced by cycasin were transplanted into hamsters, and 5 transplants were successful. Four of the transplantable lines were taken from intrahepatic bile duct carcinomas and 1 was taken from an anaplastic liver cell carcinoma. Hamsters given cycasin also developed gall bladder carcinomas, kidney tumors, intestinal tumors and malignant lymphoma but these lesions were rare.

- 1766 CHROMOSOMAL MUTATIONS BY AZATHIOPRINE IN HUMAN LEUKOCYTES *IN VITRO*. (Ger.) Hampel, K. E. (Med. Clin., Polyclin., Free U. Berlin, Germany), A. Lackner, G. Schulz and V. Busse. *Z Gastroent* 9(1): 47-51, 1971.

azathioprine and 6-mercaptopurine in various solvent media were added to cultures of human peripheral leukocytes to test whether these agents induce chromosomal mutations *in vitro*. Expressed as % metaphases with chromosomal mutations, azathioprine (0.01 mg/ml) in "oximazon" or in butanol induced, resp., mutation values of 60-73% and 12-19%, both significantly greater than controls (0-3%). Addition of 0.1 ml of plasma taken from rats 1 hr after treatment with 125 mg/kg azathioprine i.v. to leukocyte cultures also showed significantly increased values (12-14%), as did a homogenate of the commercial tablet form of azathioprine, murel (0.007 mg/ml) and 6-mercaptopurine (0.006 mg/ml) both in "oximazon" (31-48% and 20-28%, resp.). When test substances were dissolved either in water (pH 8), acetone or polyethylene glycol, the values obtained were not significantly above control levels, indicating that these solvents, unlike "oximazon", do not facilitate cell wall permeation; "oximazon" alone did not induce significant chromosomal mutations in leukocyte cultures.

767 CARCINOGENIC EFFECTS OF 3,3'-DICHLORO-4,4'-DIAMINO-DIPHENYL ETHER IN RATS. (Ger.) Steinhoff, D. (Inst. Exp. Path., Farbenfabriken Bayer AG, Wuppertal-Elberfeld, Germany) and E. Grundmann. *Naturwissenschaften* 57(12):676, 1970.

Forty Wistar rats (20 males and 20 females) were injected s.c. with 3,3'-dichloro-4,4'-diaminodiphenyl ether (250-1000 mg/kg) once weekly (or at longer intervals for the higher doses) for 190 days and a total dose of 10.5 g/kg. Thirty-seven rats which died by day 300 had developed a total of 65 malignant and 2 benign tumors. There were 1 auditory canal carcinomas, and the remaining tumors were not localized in any specific organ; no liver tumors were observed. The longest survival period for treated rats was 545 days. Only 1 of 50 control rats had died at this time and no tumors were found in these animals.

768 INCREASED TUMOR INCIDENCE-RATE IN RATS AFTER INHALATION OF A HIGH-POLYMERIC, WATER-SOLUBLE, SYNTHETIC SUBSTANCE. (Ger.) Weller, H. (Med. Dept., Silicosis Res. Inst., Mining Assoc., Bochum, Germany). *Z Ges Exp Med* 154(3):235-246, 1971.

Prague-Dawley rats were treated with inhalation of an aerosol of poly-2-vinylpyridine-N-oxide (PVNO) in a concentration of 75 mg m⁻³ after dusting or without dust for 20 or 180 min for 5 days/wk for 18 months. Other rats were exposed to aluminum chloride aerosol with and without dust; control rats were treated to dust inhalation or were untreated. Thirteen percent of rats inhaling PVNO developed tumors, while 2.7% of all groups not inhaling PVNO developed tumors. PVNO-treated animals developed a large number of lung tumors, usually more than 1 tumor per animal, as well as tumors in other areas including skin, liver and esentery. Tumor incidence in rats inhaling PVNO only for 180 min/day was 7.9%.

1769 THE EFFECT OF CHRONIC ESTROGENIC STIMULATION ON THE SQUIRREL MONKEY CERVICAL EPITHELIUM. (E.) Graham, C. E. (Yerkes Reg. Primate Res. Ctr., Emory U., Atlanta, Ga.) and S. L. Manocha. *Virchow Arch Zellpath* 7(2-3):147-156, 1971.

Changes in the cervical epithelium of the squirrel monkey were observed in animals given s.c. implanted pellets of estradiol benzoate and cholesterol (1-3 months) or diethylstilbestrol (13-14 months) in concentrations ranging from 10% estradiol and 90% cholesterol to 95% estradiol and 5% cholesterol. Pellets were implanted in the monkeys' thighs or in their backs. Controls treated with cholesterol only were given injections of 0.023 mg estradiol benzoate for 3 days starting 5 days before sacrifice. In controls, the stratified squamous epithelium of the vagina and cervix proliferated and thickened, and the squamocolumnar junction became abrupt. The same effects were produced in monkeys given implanted pellets containing 10 or 95% estradiol; but the thickening of the stratified epithelium was considerable. Monkeys given implanted pellets of 100% diethylstilbestrol for periods of 5 or more months showed several small isolated foci of partially cornified stratified epithelium; the size of these foci varied, and the larger ones penetrated the columnar epithelium and underwent desquamation into the lumen. These foci of stratified cells were seen only rarely in monkeys given 10-95% estradiol. Most of the foci of squamous cells anastomosed to form a reticulum continuous with the main mass of the cervical squamous epithelium. Apparently, the new squamous cells arose by outgrowth from the stratified squamous epithelium at the squamocolumnar junction rather than by squamous metaplasia of columnar cells. The glycogen content was most prominent in the intermediate layer of the cervical stratified epithelium and was depleted after treatment with diethylstilbestrol. The activity of phosphorylases and alcohol dehydrogenase was enhanced in estrogen-stimulated animals.

1770 NUCLEIC ACID METABOLISM OF AN ESTROGEN-DEPENDENT CARCINOMA OF THE ADRENAL CORTEX OF THE RAT. (E.) Redman, L. W. (Cancer Res. Ctr., U. British Columbia, Vancouver, Canada), M. R. Garland, M. Thompson, T. Ng and J. F. Richards. *Cancer Res* 31(3):265-269, 1971.

Young rats were given s.c. implants of an estrogen-dependent adrenal tumor and estrone-containing pellets (90% estrone and 10% cholesterol). By 5-7 days after removal of the estrone pellet, the dimensions of the tumors had decreased. In tumors deprived of exogenous estrogen stimulation and allowed to regress for 3-14 days, the incorporation of ¹⁴C-formate or ³H-cytidine into DNA had decreased to 5-30% of the incorporation rate seen in actively growing tumors. In rats which were restimulated by implantation of new estrone pellets or by an injection of estradiol, the incorporation of precursors into DNA recovered; 24 hr after the reimplantation of estrone pellets, incorporation of precursors into DNA was at 29.6% of the rate found in growing tumors, and incorporation of precursors into RNA was at 81% of the rate seen in

growing tumors. By 18 days after repelleting, incorporation into DNA was 90.3% of that in growing tumors. Nuclear RNA was labeled more rapidly than cytoplasmic RNA in regressing tumors than in growing tumors, suggesting that estrogen may play a role in the transport of RNA from the nucleus to the cytoplasm.

- 1771 EXCRETION OF CYCLOHEXYLAMINE, A METABOLITE OF CYCLAMATE, IN HUMAN URINE. (E.) Asahina, M. (Nat'l. Inst. Hyg. Sci., Tokyo, Japan), T. Yamaha, K. Watanabe and G. Sarrazin. *Chem Pharm Bull* 19(3): 628-632, 1971.

Five normal and 1 diabetic volunteer were given 2 g of sodium cyclamate (CHS-Na) in a single dose, after which 24 hr urine specimens were assayed over 5 days for the presence of CHS-Na and cyclohexylamine (CHA). In 3 cases, most of the CHS-Na (e.g., about 1.5 g) was excreted on the first day; 2 persons excreted maximum amounts of CHS-Na on day 2. Two of the subjects did not excrete appreciable amounts of CHA, while the other 3 excreted between 0.4-0.8 g of CHA from day 2 to day 5. Approximately 33-81% of the ingested CHS-Na as such and 1-18% as CHA were recovered from the urine of subjects. In a related experiment, urinary excretion of CHS-Na and CHA was monitored in 50 volunteers (49 men, 1 woman) eating normal meals during a 2 month period; cyclamate was found in the urine of all volunteers in amounts ranging from 1-700 mg/day. Forty-three of the volunteers excreted CHA, 9 of them more than 10 mg.

- 1772 CHANGES OF STABILITY AND CONFORMATION OF DNA FOLLOWING THE COVALENT BINDING OF A CARCINOGEN. (E.) Fuchs, R. (Ctr. Res. Macromolecules, Strasbourg, France) and M. Daune. *FEBS Letters* 14(4): 206-208, 1971.

Native calf-thymus DNA was reacted with N-acetoxy-acetylaminofluorene and analyzed for melting profiles. Melting curves for the modified DNA obtained at 305 nm in which 31% of the total guanine had reacted with carcinogen revealed a linear increase in temperature at a rate of 1° C/min. The T_m at 260 nm and 305 nm decreased linearly with the amount of modified guanine; the T_m value at 260 nm was always lower than at 305 nm. Extrapolation of the curves to 100% of reacted guanines gave T_m of DNA consisting only of A-T pairs. It is likely that the carcinogen reacts preferentially with G-C rich regions of DNA.

- 1773 REACTIVITIES OF THE CARCINOGENS, N-HYDROXY-2-FLUORENYLACETAMIDE AND N-HYDROXY-3-FLUORENYLACETAMIDE, WITH TISSUE NUCLEOPHILES. (E.) Zieve, F. J. (VA Hosp., Minneapolis, Minn.) and H. R. Gutmann. *Cancer Res* 31(4):471-476, 1971.

Yeast tRNA was incubated with labeled N-hydroxy-2-fluorenylacetamide (or N-hydroxy-3-fluorenylacetamide) and soluble proteins from rat liver for 1 hr; the tRNA was extracted and assayed as the K^+ salt.

The data indicated that the unpurified soluble fraction of rat liver as well as unpurified tRNA from yeast contained low-molecular-wt compounds that inhibited the binding of N-hydroxy-2-fluorenylacetamide; purification of the tRNA increased the binding 25%. Comparison of the N-hydroxy-2-fluorenylacetamide with the N-hydroxy-3-fluorenylacetamide gave values of 3.36 and 4.66 compared to values of 0.23 and 0.08 nanoatoms ^{14}C or 3H bound/mg tRNA, resp., with a slight decrease in values with the addition of tRNA for both compounds. A slight decrease in binding values was seen with the addition of cofactors and tRNA for the first compound and a slight increase for the second compound. Since esterification of N-hydroxy-3-fluorenylacetamide to the sulfate was not accomplished (or the sulfate is unreactive) the question remains whether esterification to a sulfate is the molecular mechanism of the carcinogenic actions of this compound.

- 1774 THE REACTION OF THE CARCINOGEN N-ACETOXY-2-ACETYLAMINOFLUORENE WITH DNA AND OTHER POLYNUCLEOTIDES AND ITS STEREOCHEMICAL IMPLICATIONS. (E.) Kapuler, A. M. (Inst. Physico-Chem. Biol., Paris, France) and A. M. Michelson. *Biochim Biophys Acta* 232(3):436-450, 1971.

The reaction of N-acetoxy-2-acetylaminofluorene (AAAF) with guanosine, deoxyguanosine, adenosine and *Micrococcus lysodeikticus* DNA was studied by spectroscopic and chromatographic techniques. Methods for quantitation of guanosine-AAF, deoxyguanosine-AAF and other nucleotide-AAF complexes are described. The native DNA reacted more rapidly with AAAF than the synthetic ribo- and deoxyribopolynucleotide complexes by a factor of 10; double-helical homopolynucleotide complexes reacted less readily than single-stranded polymers. Reaction of AAAF with DNA occurred at both adenosine and guanosine residues, although adenosine residues in homopolymer double-helical complexes were resistant. This finding suggests that reaction of AAAF in DNA first occurs at guanosine residues followed by adenosine residues in the vicinity. Studies of static models of DNA predict that C-8 of purine residues will be protected from chemical reaction by virtue of its relative inaccessibility due to the *anti*-conformation and the reactivity of DNA with AAAF implicates a dynamic aspect of the double helix; it is likely that guanosine residues conjugated to AAAF are preferentially in the *syn* rather than the *anti* conformation.

- 1775 THIOACETAMIDE INDUCED CHANGES IN RAT LIVER RNA CONTENT. (Ger.) Kullmann, R. (Path. Inst. U. Freiburg, Germany), G. Kiefer and W. Sandritter. *Beitr Path* 143(1):1-13, 1971.

Cytophotometry was used to examine RNA metabolism in liver cells of rats given 25 mg/kg doses of thioacetamide daily for 8-30 days. RNA concentrations in the center of the liver lobule or its periphery were comparable to concentrations in untreated rat livers however, total cytoplasmic RNA content in centrally located liver cells of treated rats was reduced.

compared to total RNA content in livers of untreated rats. Peripheral liver cells in treated rats had higher than normal contents of cytoplasmic RNA. The centrally located liver cells appeared to be more affected by thioacetamide than were peripheral cells, and this effect was produced by a blockage of RNA transport out of nucleoli of centrally located cells. The increase in cytoplasmic RNA in peripheral cells may have represented compensation for the blockage of RNA from central cells.

- 1776 MYCOTOXINS OTHER THAN AFLATOXINS: TUMOR-PRODUCING POTENTIAL AND POSSIBLE RELATION TO HUMAN DISEASE. (E.) Louria, D. B. (New Jersey Coll. Med. Dent., Newark), J. K. Smith and G. C. Finkel. *Ann NY Acad Sci* 174(2): 583-591 1970.

The effect of administration of sonicates or supernates of alternaria and *Aspergillus niger* to 4-6-wk-old mice was studied. A statistically significant increase in leukemia resulted among mice so treated, with the highest incidence occurring among those that were inoculated s.c. for alternaria (75%) and those that were force-fed for *Aspergillus niger* (64%). Aflatoxin-like substances were found in cigarette-smoke condensate when studied by thin-layer chromatography and ultraviolet analyses, but these compounds seemed to be less lethal for embryonated eggs than previously identified aflatoxins.

- 1777 ACUTE AFLATOXIN B₁ TOXICITY IN THE MACAQUE AND ITS SIMILARITIES TO REYE'S SYNDROME. (E.) Bourgeois, C. H. (SEATO Med. Project, Bangkok, Thailand), R. C. Shank, R. A. Grossman, D. O. Johnsen, W. L. Wooding and P. Chandavimol. *Lab Invest* 24(3):206-216, 1971.

Macaque monkeys (*Macaca fascicularis*) were fed capsules made up of 0.5, 1.5, 4.5, 13.5 or 40.5 mg/kg of aflatoxin B₁; the aflatoxin had been produced by *A. flavus* isolated from rice eaten by a Thai child who died with Reye's syndrome. The 1.5 mg and under doses of aflatoxin were not fatal to monkeys; however, 1 of 4 monkeys given 4.5 mg and all monkeys given more than 4.5 mg died within 149 hr, with the first deaths occurring 67 hr after aflatoxin treatment. Symptoms included vomiting, anorexia and lethargy. All fatal cases of aflatoxin poisoning showed marked alterations in serum glucose, nonesterified fatty acids, phospholipids and transaminases by 72 hr after treatment. Serum glutamic-oxaloacetic transaminase and serum glutamic-pyruvic transaminase were markedly elevated in fatal cases, as was the level of nonesterified fatty acids. Phospholipids and glucose were decreased 2- and 5-fold, resp., in treated animals. The liver wt of aflatoxin-treated macaques decreased 15% below the wt of control animals, and livers of aflatoxin-treated animals showed fatty degeneration of hepatocytes, decreased liver glycogen, liver cell necrosis and bile duct hyperplasia. Fatty degeneration was also observed in the hearts and kidneys of affected macaques. The similarities between the toxic reactions of the monkeys to aflatoxin and the clinical and metabolic symptoms of children affected with Reye's syndrome was striking.

- 1778 A SUBACUTE EXPOSURE OF BEAGLE DOGS TO AFLATOXIN. (E.) Armbrrecht, B. H. (Bur. Vetr. Med., Beltsville, Md.), J. N. Geleta, W. T. Shalkop and C. G. Durbin. *Toxic Appl Pharmacol* 18(3):579-585, 1971.

Beagle dogs were given 1, 5 or 20 µg/kg of aflatoxin daily, 5 days/wk for 10 wk. Early consequences of 20 µg/kg of aflatoxin feeding included inappetence, yellow-orange urine and icteric serum. Hemoglobin, hematocrit and erythrocyte values were similar in the different dosage groups. Prothrombin time was significantly increased in dogs given 20 µg/kg of aflatoxin compared to dogs in lower dosage groups; Alkaline phosphatase was increased 4-8-fold in the 20 µg/kg group compared to untreated controls and lower dosage groups. α₂-Globulin and β₂-globulin were decreased in the high aflatoxin dosage group compared to the control and low dosage groups. In livers of the group of dogs given 20 µg/kg aflatoxin there were moderate bile duct proliferation, bile pigment accumulation in the portal areas and multiple vascular channels around the central and portal veins.

- 1779 TERATOGENIC ACTION OF AFLATOXIN B₁, PALMOTOXIN B₀ AND PALMOTOXIN G₀ ON THE CHICK EMBRYO. (E.) Bassir, O. (Dept. Biochem., U. Ibadan, Nigeria) and A. Adekunle. *J Path* 102(1):49-51, 1970.

Aflatoxin B₁, palmotoxin B₀ and palmotoxin G₀ were each injected into the yolk-sac of chick embryos; the dosage of aflatoxin B₁ and palmotoxin B₀ was 0.2-0.6 µg, while the dosage of palmotoxin G₀ was 2.0-6.3 µg. Palmotoxin B₀ produced malformations of the beak and skull, while aflatoxin B₁ induced malformations of the limbs, especially abnormal twisting of limbs; similar results were noted in some chicks hatching from eggs injected with palmotoxin B₀. Other effects of these 2 agents included enlargement and pallor of the liver and retardation of growth. Palmotoxin G₀ administered in amounts of 0.2-1.5 µg produced no obvious ill effects; higher doses induced 14-21% abnormal embryos, as compared to 83-94% abnormal embryos induced by palmotoxin B₀, and 65-90% abnormal embryos produced by aflatoxin B₁.

- 1780 HISTOCHEMICAL HEPATIC CHANGES IN RATS WITH ACUTE AFLATOXIN INTOXICATION. (Fr.) Lageron, A. (Hosp. St. Antoine, Paris, France), W. Schwarzmann and J. Caroli. *Rev Medicochir Mal Foie* 46(1):33-37, 1971.

Crystalline aflatoxin B₁ in dimethylsulfoxide given in a single dose (7 mg/kg) by gavage to male Wistar rats, showed histochemical hepatocellular changes measured at 4 intervals from 4-72 hr. In the cytoplasm, the most important change was the marked reduction of glycogen in periportal hepatocytes. There was a reduction in the activities of glucose-6-phosphate dehydrogenase and in 6-phosphoglucose dehydrogenase which then returned to normal levels in 72 hr; RNA remained slightly diminished through this period. Mitochondrial nicotinamide-adenine-dinucleotide-phosphate-tetrazolium-reductase, ATPase,

isocitrate dehydrogenase, and glutamate dehydrogenase as well as glucose-6-phosphatase of the endoplasmic reticulum all showed persistently decreased activity. In lysosomes there was a rise in β -glucuronidase activity, while acid phosphatase showed a decrease, followed by a rise.

- 1781 IS AFLATOXIN CARCINOGENIC IN MAN? THE EVIDENCE IN SWAZILAND. (E.) Keen, P. (South African Inst. Med. Res., Johannesburg) and P. Martin. *Trop Geogr Med* 23(1):44-53, 1971.

An investigation of the incidence of primary liver cancer in Swaziland indicated that 11 of 90 cases reported between 1964-1968 occurred in the "highveld" area of the country (the western third), 34 cases occurred in the "middleveld" (the central third) and 44 cases occurred in the "lowveld" (the eastern third). These figures yielded risks for populations in the highveld, middleveld and lowveld of 1.0, 1.8 and 4.5, resp., for developing hepatic carcinoma. The condition was more common among Shangaan immigrants than among Swazi tribesmen living in the same areas. The content of the aflatoxin-producing fungus *Aspergillus flavus* in groundnuts from various parts of Swaziland was found to have the same distribution as liver cancer incidence; 20% of groundnuts sampled contained aflatoxin in the highveld, 57% contained aflatoxin in the middleveld, and 60% contained aflatoxin in the lowveld. While groundnuts are eaten by inhabitants in all parts of Swaziland, it was found that in areas of widespread liver cancer, groundnuts were prepared and stored in such a way as to conduce to the infestation of the groundnuts by *A. flavus*. Furthermore, Shangaan tribesmen, who have a high incidence of liver cancer were found to eat groundnuts more regularly than Swazi tribesmen, who have a relatively low incidence of liver cancer. While the findings clearly suggested that aflatoxin was related to liver cancer in Swaziland, the aflatoxin hypothesis could not be extended abroad to account for the incidence of liver cancer in other parts of the world.

- 1782 MITOTIC RATES OF REGENERATING LIVER PARENCHYMA AND DAB INDUCED PRIMARY HEPATOMA. (E.) Bertalanffy, F. D. (Fac. Med. U. Manitoba, Winnipeg, Canada), J. C. W. Parrott and M. L. Ozohan. *Acta Anat* 77(2):216-237, 1970.

The 6-hr mitotic rate of the liver of normal intact rats was $0.02 \pm 0.02\%$; after excision of 70% of the liver, the mitotic rate of parenchyma cells remained at near normal levels until 24-30 hr after hepatectomy, at which time it increased to 0.70% at 30 hr and to a maximum value of 16.0% at 36 hr. After attaining maximum values, the mitotic rate in the parenchyma of hepatectomized rats declined, reaching zero by 8 days after hepatectomy. Mitotic activity in partially hepatectomized rats fluctuated during the day, and was highest during daylight hours and lowest at night. When mitotic rates were determined for the livers of parabiotically joined rats following partial hepatectomy of 1 of them, it was found that hepatectomy of 1 rat augmented the mitotic rate in the intact liver of its parabiotic twin. Hepatomas induced in

rats by chronic feeding with 0.06% preparations of 4-dimethylaminoazobenzene manifested diverse levels of mitotic activity, mitotic rates ranging from 1.63-10.85% in this group. Daily mitotic rates for grade II hepatomas were 19%, and 29% for grades III-IV hepatomas. Mice given implants of the transplantable mouse hepatoma BW7756 showed mitotic rates of 28 and 31% approximately 28-35 days following tumor transplantation.

- 1783 THE ACUTE EFFECT OF AMINOAZOBENZENE AND SOME OF ITS DERIVATIVES ON RNA POLYMERASE ACTIVITY IN ISOLATED RAT LIVER NUCLEI. (E.) Wu, S. Y. (Dept. Path., U. Washington, Seattle) and E. A. Smuckler. *Cancer Res* 31(3):239-247, 1971.

Male rats were given aminoazobenzene (AB), N,N-dimethyl-4-aminoazobenzene (DAB), 2-methyl-N,N-dimethyl-4-aminoazobenzene (2-me-DAB), or 3'-methyl-N,N-dimethyl-4-aminoazobenzene (3'me-DAB) in amounts of 300 mg/kg via gastric intubation, and the capacity of liver cell nuclei to form RNA was observed by measuring tritiated uridine triphosphate (UTP) incorporation into liver cell nuclei. UTP incorporation was enhanced when measured in nuclei isolated from rats treated with DAB or AB; the former agent produced maximal incorporation levels at 24 hr after treatment (4720 cpm/0.1 mg DNA), and AB was maximally stimulatory after 12 hr (4180 cpm). DAB produced a more pronounced and sustained stimulation of UTP incorporation than the other agents. After 48-72 hr after carcinogen treatment, UTP incorporation levels returned to those seen in untreated controls. Rats given repeated doses of DAB showed further potentiation of UTP incorporation. Increased endogenous polymerase activity of liver chromatin was found following azo dye treatment and was maximal following DAB; increased polymerase activity in liver chromatin was also produced by AB. The RNA-polymerase enhancing effects of azo dye treatment may have been due to the carcinogenic transformation effected by azo dyes, or may have been due to the toxicity of the dyes, resulting in alterations of genetic expression.

- 1784 LYSOSOMES OF RAT LIVER AND DAB CARCINOGENESIS. (E.) Takano, T. (Fac. Pharm. Sci., U. Tokyo, Japan), N. Kato, S. Kunimoto-Miyata, S. Goto, S. Ohkuma, D. Mizuno, T. Kitagawa and T. Yokoyama. *Int J Cancer* 7(2):346-352, 1971.

Rats fed for 40 days with 0.06% 4-dimethylaminoazobenzene (DAB) developed nodules and degenerated cells in their livers. Hepatomas had developed by 90 days after commencement of the DAB regimen. The total activity of RNase in liver lysosomes increased by 50% after DAB feeding commenced. Thereafter, RNase activity remained constant. The lysosomal S/P fraction (the ratio of supernatant and precipitated lysosomal fractions prepared by centrifugation) was determined to investigate the intracellular location of lysosomal enzymes including RNase and β -glucuronidase. The S/P ratio increased 2- or 3-fold with DAB feeding up to day 40 and remained constant thereafter.

- 1785 ULTRASTRUCTURAL CHARACTERISTICS OF HEPATOMAS INDUCED BY AZODYES IN THE WISTAR RAT: II. ELECTRON MICROSCOPY OF THE HEPATOMA N-13 A. (Sp.) Peydro Olaya, A. (Fac. Med. Valencia, Spain). *Med Esp* 64(380):283-311, 1970.

Solid and ascitic transplantable tumors induced in rats by chronic administration of 4-dimethylaminoazobenzene were examined by electron microscopy; the ascitic tumor was found to harbor cytosomes different from inclusions seen in other ascites tumors. These cytosomes may have been produced by the granular endoplasmic reticulum; they were proteinaceous and had a crystalline filamentous structure. The ascites tumors appeared as poorly differentiated ascites hepatomas with cells having lobulated nuclei and large nucleoli. Small spherical mitochondria were common and a granular endoplasmic reticulum with poorly developed vesicular forms and highly developed Golgi apparatus were observed. Abundant cytoplasmic glycogen also characterized these ascites tumors.

- 1786 QUANTITATIVE STUDIES OF EARLY CYTOLOGICAL ALTERATIONS INDUCED IN RAT LIVER BY 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE, AS AFFECTED BY 3-METHYLCHOLANTHRENE. (E.) Harman, J. W. (Dept. Path., U. Coll. Dublin, Ireland). *J Path* 102(2):69-85, 1970.

Experiments with male Wistar rats weighing 120-140 g were initiated by incorporation of dye and/or hydrocarbon into the basal diet ration. At necropsy, the right lobe of the liver, the spleen and both kidneys were excised for microscopic examination. The dyed rats were generally sluggish; they developed diarrhea and their fur was ruffled and contaminated with feces. At necropsy, the liver appeared yellow and faintly mottled without showing necrosis or fibrosis. All other tissues were stained a deep yellow, but were otherwise normal. Within 24 hr after the commencement of dye ingestion, structureless hyaline inclusions were noted. These inclusions were most numerous after dye feeding for 10 days and they became less numerous in the following week. Basophilia of the cytoplasm of all parenchymal cells became less intense soon after appearance of hyaline inclusions. When both dye and hydrocarbon were supplied together, the inclusions were less prominent in the cells of the central zone, whereas the peripheral parenchymal cells became slowly and progressively loaded with the same type of inclusions. Further, the loss of cytoplasmic basophilia in the periportal cells was much more marked. After approximately 10 days there were 3 prominent changes (the 2nd phase): ductule hyperplasia, appearance of "new" cells and development of minute foci of atypical parenchymal cells. Simultaneous feeding of dye and hydrocarbon altered the histological localization of the parenchymal cell lesion to the periphery of the lobules (1st phase) and suppressed the 2nd phase. The results indicated that the topographical location of the early parenchymal lesions was important for induction of later ductule and parenchymal lesions and that the hydrocarbon prevented lesions by modifying the lobular distribution of the early parenchymal reaction.

- 1787 PRESENCE OF DMBA-³H IN THE MOUSE OVARY AND ITS RELATION TO OVARIAN TUMOUR INDUCTION. (E.) Krarup, T. (Finsen Inst., Copenhagen, Denmark) and H. Loft. *Acta Path Microbiol Scand* 79(2):139-149, 1971.

Mice were given i.p. or p.o. doses of ³H-7,12-dimethylbenz(a)anthracene (DMBA) and killed 6 hr, 6 days or 2½ months thereafter; on autopsy, specimens of ovarian tissue as well as other tissues were examined for presence of the labeled carcinogen. In ovaries of mice not given DMBA, the number of small oocytes decreased from 6600 at 22 days of age to 3200 at 3 months of age, while in mice given p.o. DMBA, the number of small oocytes decreased from 5100 on day 1 after treatment to 1000 on day 14. I.P. injection of DMBA produced a more marked decline in number of small oocytes. Fat, ovary, adrenal, liver, muscle and brain tissue were examined for ³H-DMBA; in all tissues the maximum amount of label was found 6 hr after feeding with the carcinogen. The lipid-soluble fractions of tissues usually contained more label than the insoluble fractions, and fat contained more label (8728 cpm/mg) than other tissues, while the brain contained the least (417 cpm/mg). The maximum level of radioactivity in tissues was higher in all cases after i.p. administration of the carcinogen than after p.o. administration. Three unilateral ovarian tumors developed in 3- and 5-month-old animals. Only in liver tissues were lipid-soluble and insoluble fractions of tritium of comparable levels. The carcinogenic effect of DMBA on the mouse ovary appears to be due to the parent hydrocarbon rather than to its metabolic products. This carcinogenic effect seemed to be produced immediately upon the application of the carcinogen and consisted in the destruction of small oocytes which led in turn to neoplastic ovarian development. Prolonged retention of DMBA in the ovary after i.p. injection was thought to have no effect on neoplastic development.

- 1788 EXPERIMENTAL ORAL MALIGNANT LYMPHOMA USING ALVEOLAR SOCKET CARCINOGEN IMPLANTATION. (E.) Mesrobian, A. Z. (Sch. Dent., U. Detroit, Mich.) and G. Shklar. *J. Periodont* 42(2):105-108, 1971.

The mandibular first left molar was extracted from the jaw of 40 male and female hamsters; in 20 animals, the root of the tooth was dipped into a powder preparation of pure 7,12-dimethylbenz(a)anthracene (DMBA) and replaced into its alveolar socket position. Control hamsters were untreated, or had molars extracted and replaced without DMBA treatment. All animals undergoing molar extraction showed inflammation of the jaw in the affected region; by 4 wk after surgery, controls showed diminishing inflammation together with lymphoma development. By 8 and 12 wk after surgery, controls had returned to normal, and DMBA-treated animals had developed malignant lymphoma in the submandibular area. Lymphoma arose in periosteal soft tissue and contained many lymphoblastic cells. Malignant lymphomatous lesions were found within the mandible itself in marrow spaces adjacent to the replanted molar tooth. Two

lymphomatous hamsters also developed invasive epidermoid carcinoma of the submandibular region.

- 1789 EFFECT OF HORMONE STIMULATION, DOSE, AND TIME OF ADMINISTRATION OF CARCINOGEN ON CARCINOGEN-INDUCED MAMMARY TUMORS FROM PRENEOPLASTIC NODULE OUTGROWTHS. (E.) Medina, D. (Baylor Coll. Med., Houston, Tex.). *J Nat Cancer Inst* 46(4):909-916, 1971.

The tumorigenic effects of 7,12-dimethylbenz(a)anthracene (DMBA) and urethan and of γ -irradiation were analyzed on nodule outgrowth line D1, one of a series of BALB/c mouse mammary tumor virus-free outgrowths. DMBA and urethan treatment produced 68% and 83% tumor growth, whereas irradiated outgrowths produced only 23% tumor growths. Hormone stimulation (pituitary isograft) enhanced the effects of DMBA, whereas hormone effects with urethan administration failed to show statistically different results and γ -irradiation was inhibited in its ability to produce tumors. Time of administration and dosage determined the response of outgrowths to urethan; exposure at 3-5 wk after transplantation resulted in greatest incidence of outgrowth. Apparently the nature of the cell population exposed to the carcinogen determined the response of the outgrowths.

- 1790 THE EFFECT OF THYROACTIVE SUBSTANCES ON THE INDUCTION OF CERVICO-VAGINAL AND VULVAL TUMOURS IN CASTRATE RATS AT VARIOUS LEVELS OF CARCINOGENIC TREATMENT. (E.) Glucksmann, A. (Strangeways Res. Lab., Cambridge, England) and C.P. Cherry. *Brit J Cancer* 24(4) 769-784, 1970.

The effect of L-thyroxine and methylthiouracil on thresholds for carcinogenesis of 7,12-dimethylbenz(a)anthracene (DMBA)-induced cervico-vaginal and vulval tumors was studied in castrate hooded rats of the Lister strain by p.o. administration of the thyroactive substances. At 40 paintings of cervix, vagina and introitus with DMBA, dose-response curves show that both methylthiouracil and L-thyroxine make a significant difference in incidence of tumor induction. Sarcomas reached a peak incidence of 25% with 20 doses of carcinogen in nonmedicated rats and rose to 90% with the use of thyroactive drugs. Methylthiouracil accelerated the formation of squamous cell vulval tumors at lower doses of DMBA, while L-thyroxine slowed the rate of tumor induction with longer DMBA treatment. Central regulatory factors must be responsible for the effects of variations in doses of DMBA on carcinogenesis.

- 1791 EFFECTS OF 7,12-DIMETHYLBENZ[a]ANTHRACENE ON RNA POLYMERASE IN ISOLATED MAMMARY GLAND CELL NUCLEI. (E.) Tominaga, T. (Roswell Park Mem. Inst., Buffalo, N. Y.), T. L. Dao and P. R. Libby. *Proc Soc Exp Biol Med* 136(3):694-697, 1971.

Rats of both sexes were fed 20 mg of 7,12-dimethylbenz(a)anthracene(DMBA) on 1, 2 or 4 days prior to killing, and nuclei from mammary gland cells were assayed for Mg^{2+} -activated RNA polymerase, and Mn^{2+} -

$(NH_4)_2SO_4$ -activated RNA polymerase. In male rats enzyme activity values for the DMBA-treated rats were not significantly different from values for untreated controls. No significant changes were found in female rats in the levels of the Mg^{2+} -activated polymerase before and after DMBA treatment. In female rats, the Mn^{2+} -ammonium sulfate-activated enzyme showed inhibition relative to control values at 1 and 2 days after DMBA feeding, and increased thereafter to exceed control values. At 1 day after DMBA feeding Mn^{2+} -ammonium sulfate-activated enzyme levels in control and DMBA-fed rats were, resp., 36.46 and 25.02 μ moles of UTP incorporated into RNA/10 min/mg DNA. At 4 days after DMBA feeding, control and DMBA-fed levels for this enzyme were resp., 34.70 and 46.88 μ moles TUP/10 min/mg.

- 1792 THE EFFECT OF DISTAL SMALL BOWEL BYPASS AND RESECTION ON 7,12-DIMETHYLBENZ[a]ANTHRACENE PRODUCED MAMMARY CARCINOMA IN THE RAT. (E.) Weinberg, M. (Temple U. Hlth. Sci. Ctr., Philadelphia, Pa.), L. Goldman, M. Gruenstein, D. R. Meranze and M. B. Shimm. *J Surg Res* 11(2):101-103, 1971.

Female rats were fed 10 mg of 7,12-dimethylbenz(a)anthracene (DMBA) 1 wk before or after undergoing distal small bowel bypass or resection; in 1 group of rats, distal small bowel bypass was effected 1 wk prior to concomitant administration of DMBA and cholic acid. The wt and serum cholesterol of animals in the various groups were similar. Ninety-two percent of intact control rats given DMBA developed mammary adenocarcinomas. Thirty-seven percent of the rats undergoing distal small bowel bypass followed by DMBA developed tumors, and 97% of the rats given DMBA followed by bypass developed mammary tumors. Sixty-one percent of rats given DMBA prior to resection developed tumors, and 65% of rats given DMBA and cholic acid following bypass developed tumors.

- 1793 TUMOR-PROMOTING ACTIVITY OF TOBACCO EXTRACTS. (E.) Bock, F. G. (Roswell Park Mem. Inst., Orchard Park, N. Y.). *J Indian Med Prof* 17(3):7561-7564, 1970.

Commercial cigarette tobacco was extracted with aqueous barium hydroxide solution and painted on the skin of mice previously treated with a single dose of 125 μ g of 7,12-dimethylbenz(a)anthracene. Mice were given extract from $\frac{1}{2}$ g of tobacco daily. The tobacco extract was seen to have marked tumor promoting effects; the percentage of mice with tumors which had been treated with carcinogen and tobacco extract increased from 12% at wk 10 of extract treatment to 30% by wk 26. In contrast, less than 1% of the mice given carcinogen only had developed tumors by week 26. Attempts to isolate the tumor-promoting agents in the tobacco extracts indicated that 2 agents were at work; one agent had a high molecular wt and was insoluble in methanol and the other had a low molecular wt and was soluble in methanol. The high molecular wt component was thought to be a tobacco pigment. Extracts of cigarettes made by 5 American and 2 British companies produced tumors in 11-44% of mice; the chemicals added to the American cigarettes during manufacture

did not increase tumorigenicity significantly over that of British cigarettes, which are relatively additive-free. The tumor promoting properties of cigarette tobaccos were thought to be due either to chemicals used in growing the tobacco or to chemical changes occurring in the tobacco leaf during the curing and aging of the leaf. Extracts of uncured fresh tobacco leaves raised without chemical insecticides or suckering agents had only weak efficacy as tumor-promoting agents.

1794 THE DEVELOPMENT OF DIMETHYLBENZANTHRACENE-INDUCED MAMMARY GLAND TUMORS IN RATS WITH DIFFERENT HORMONAL CONDITIONS. (Rus.) Turkevich, N. M. (Res. Inst. Exp. and Clin. Oncol. Kiev, U.S.S.R.) and Ya. D. Matveychuk. *Vop Onkol* 17(1): 41-45, 1971.

The development of dimethylbenzanthracene (DMBA)-induced mammary gland tumors under various estrous conditions as affected by daylight hours or by reserpine in white female rats was investigated. Three groups of rats were used: group I was subjected to a 14 day study of vaginal smears before and after reserpine treatment (1 mg/kg s.c. single dose) followed by DMBA (2 mg i.v. 3 times at 6 day intervals) given 2 wk after reserpine; group II underwent a 14 day study of the estrous cycle prior to DMBA administration using dosage as above; in group IIIa, administration of DMBA was followed by an estrous cycle study during the month of August and in group IIIb DMBA administration followed an estrous cycle study during November, January and February. The experimental period lasted 6 months after the last administration of DMBA when 50% of the animals had developed carcinomas of the mammary gland. The rats which developed tumors had 4 estrous days in November while animals which developed no tumors had 7 estrous days. The number of estrous days increased during January and February from 7 to 9 in rats which did not develop tumors and from 4 days to 10 days in animals which developed carcinomas. Reserpine decreased the number of estrous days from 8 to 6 and DMBA reduced the estrous days from 7 to 3 in rats which developed tumors and from 7 days to 6 days in rats which developed no tumors. A direct relationship between the variability of the estrous cycle and DMBA carcinogenesis could be established.

1795 INHIBITION OF MURINE SUBCUTANEOUS AND INTRAVENOUS BENZO(rst)PENTAPHENE. CARCINOGENESIS BY SWEET ORANGE OILS AND d-LIMONENE. (E.) Homburger, F. (Bio-Res. Inst., Cambridge, Mass.), A. Treger and E. Boger. *Oncology* 25(1): 1-10, 1971.

Three groups of 50 male C57BL/6 Jax mice were injected s.c. with 25 µg of benzo(rst)pentaphene (DBP) in 0.1 ml tricapylin and 50 control animals received 0.1 ml of tricapylin alone. Twenty-four hr later, 0.2 ml of one or the other of 2 types of sweet oil of orange was administered s.c. to a group of 50 mice. None of the mice receiving

orange oil alone or tricapylin alone developed tumors in the 2-yr observation period. The tumor appearance rate in animals given DBP alone was twice as high as in animals given DBP and sweet orange oil. When injection sites taken from these mice were transferred into fresh hosts which were given s.c. injections of sweet orange oil 24 hr later, the rate of tumor development was affected in the same manner as in animals administered DBP directly. Of 50 female A/Jax mice injected in the tail vein with DBP alone, 74% developed lung adenomas, while those given DBP and sweet orange oil had an adenoma incidence of 44%. Limonene reduced the DBP tumorigenicity to 40%, while limonene hydroperoxide had less effect and 5-fluorouracil had no effect.

1796 CIGARETTE SMOKE: STIMULATORY EFFECT ON METABOLISM OF 3,4-BENZOPYRENE BY ENZYMES IN RAT LUNG. (E.) Welch, R. M. (Wellcome Res. Lab., Burroughs Wellcome Co., Research Triangle Park, N. C.), A. Loh and A. H. Conney. *Life Sci* 10(4):215-221, 1971.

Female rats were allowed to breathe a mixture of cigarette smoke and air in a smoke-filled chamber for 1-4 hr, and the ability of the lung to hydroxylate 3,4-benzopyrene (BP) was assayed. BP-hydroxylase activity in lung was decreased 27% after 1 hr of exposure to smoke; after 2 and 4 hr of exposure, however, the enzyme activity increased 34% and 186%, resp. Rats not exposed to cigarette smoke showed no change in lung BP-hydroxylase. Actinomycin (2 mg/kg body wt) administered i.p. 30 minutes prior to smoke exposure completely blocked the increase in BP-hydroxylase following smoke exposure. Puromycin administered 1 hr prior to smoke exposure similarly prevented the increase in BP-hydroxylase, indicating that the induction of lung BP-hydroxylase activity by cigarette smoke required the synthesis of RNA and protein. After exposure to smoke for 5 hr/day for 3 days, BP-hydroxylase activity in lung and placenta of pregnant rats was increased 12- and 4-fold, resp. Enzyme inducers in the cigarette smoke may be able to reach the fetus in mothers exposed to smoke.

1797 THE STUDY OF DEVELOPMENT OF LUNG AND SKIN TUMORS IN MICE EXPOSED *IN UTERO* TO POLYCYCLIC HYDROCARBONS. (E.) Bulay, O. M. (Ankara U. Med. Sch., Turkey). *Acta Med Turcica* 7(1):3-38, 1970.

The effect of benzo(a)pyrene (12mg) and 7,12-dimethylbenz(a)anthracene (DMBA, 1-4 mg) on the fetus *in utero* was studied in Swiss Ha/ICR mice that were injected i.p. with carcinogens on the 11th, 13th and 15th days of gestation. In mice delivered by caesarean section, the incidence of pulmonary adenomas in the benzo(a)pyrene group was 71.4%, whereas in animals born spontaneously, the incidence was 58.3%. The tumors attained a diameter of 2-3 mm, were sharply circumscribed and located on the surface and covered by pleura. Skin papillomas resulted in 28.9% of the group treated *in utero* with benzo(a)pyrene and

postnatal croton oil application, compared to the control group treated with croton oil only, in which the incidence was 14.2%. High doses of DMBA with croton oil resulted in the highest percentage of skin papillomas (31.1%). *In utero* carcinogenic effects were produced by transplacental passage of polycyclic hydrocarbons.

- 1798 THE MECHANISM OF CARCINOGENESIS BY THE NEUTRAL FRACTION OF CIGARETTE SMOKE CONDENSATE. (E.) Roe, F.J.C. (Chester Beatty Res. Inst., London, England), R. Peto, F. Kearns and D. Bishop. *Brit J Cancer* 24(4): 788-806, 1970.

The carcinogenic effect of the neutral fraction of smoke condensate on mouse skin was studied in 16 groups of Swiss female SPF mice by application of various combinations of benzo(a)pyrene and the neutral fraction of cigarette smoke in acetone to skin. Treatment 3 times a wk with both agents resulted in the appearance of malignant skin tumors in 114 animals, 28 of which developed more than one tumor and 28 of which showed metastatic deposits. In single-treatments with benzo(a)pyrene a non-linear dose-response curve for carcinogenicity revealed that a single dose produced a rate of cancer incidence greater than twice the rate produced by half that dose, while a linear dose-response curve was obtained with the neutral fraction. However a higher incidence rate than the sum of the incidence rates when used alone was seen in combination. These findings suggest that the neutral fraction acts mainly on only one rate-determining step of the carcinogenic process.

- 1799 HUMAN PLACENTAL HYDROXYLATION OF 3,4-BENZOPYRENE DURING EARLY GESTATION AND AT TERM. (E.) Juchau, M. R. (Sch. Med. U. Washington, Seattle). *Toxic Appl Pharmacol* 18(3):665-675, 1971.

Hydroxylation of benzo(a)pyrene was assayed in placental tissues of women in various stages of pregnancy with differing histories of cigarette smoking; results were compared with benzopyrene hydroxylase (BPOHase) found in placental tissues of pregnant rats injected with 20 mg/kg 3-methylcholanthrene. In humans, readily detectable levels of BPOHase were found only in placental tissues of women who smoked cigarettes at term. In these subjects, the level of placental BPOHase was 70 U/mg protein/hr, while for women at term who did not smoke, placental BPOHase was 4.7 U/mg/hr. Placental BPOHase from women 8-16 wk into pregnancy measured 1.6 U/mg/hr for smokers and less than 0.4 U/mg/hr for nonsmokers. Placentas of rats not given 3-methylcholanthrene showed only minimal BPOHase activity, while placentas from pretreated rats exhibited a 12-fold increase in BPOHase. BPOHase activity in human fetal or neonatal livers was not detectable. Examination of BPOHase values for individual patients indicated that a positive correlation between gestational age and enzyme activity existed, and that a similar correlation existed between number of cigarettes smoked by mothers and placental BPOHase.

- 1800 BENZO(a)PYRENE IN THE WORKPLACE ATMOSPHERE OF COAL AND PITCH COKING PLANTS. (E.)

Masek, V. (Res. Inst. NHKG Steelworks, Ostrava-Kuncice, Czechoslovakia). *J Occup Med* 13(4):193-198, 1971.

Concentrations of benzo(a)pyrene in Czech coal and pitch coking plants were found to be maximal in the immediate vicinity of the pitch battery (3,815 µg/cubic meter of air) and were higher in the winter months than in the summer. Benzo(a)pyrene concentration in the air of the coking plants was determined by collecting filtered air samples and isolating the carcinogen by means of chromatography. Charging the coke ovens by a steam injection technique produced 10% less benzo(a)pyrene pollution than charging the ovens by gravity.

- 1801 INFLUENCE OF *CANDIDA ALBICANS* GLYCOPROTEIN ON 3-METHYLCHOLANTHRENE INDUCED MALIGNANCY IN NEWBORN RODENTS. (E.) Mankowski, Z. T. (Western Inst. Cancer Leukemia Res., Santa Monica, Calif.). *Mycopathologia* 44(2):95-100, 1971.

Newborn rats and albino noninbred mice were given s.c. injections of 166 µg of 3-methylcholanthrene (3-MC)/g body wt (rats) or 25.5 µg of 3-MC/g wt (mice); after weaning, rats and mice were injected 5 times weekly with *Candida albicans* (C.a.) glycoprotein. Animals were given either 9.5 µg or 18.5 µg C.a. glycoprotein. In the 6 months following treatment, rats given only 3-MC developed s.c. tumors in 30% of the cases, rats given 9.5 µg C.a. glycoprotein developed tumors in 65% of the cases, and rats given 18.5 µg C.a. glycoprotein developed tumors in 80% of the cases. Rats given C.a. glycoprotein as well as 3-MC developed tumors earlier than did rats given 3-MC only; 23 tumors were observed in 20 rats given C.a. glycoprotein by 5 months after treatment, and 3 tumors observed in 20 rats given 3-MC only at this time. Tumors developed by rats given C.a. glycoprotein attained larger dimensions than those developed by untreated rats. Similar results were obtained for mice, which developed a high incidence of thymomas when treated with C.a. glycoprotein and 3-MC.

- 1802 SUSCEPTIBILITY OF MAMMARY-TUMOR-VIRUS-FREE BALB/c MOUSE MAMMARY NODULE OUTGROWTH CELLS IN DNA SYNTHESIS TO 3-METHYLCHOLANTHRENE TUMORIGENESIS. (E.) Adamson, R. (Inst. Cell. Res., U. Nebraska Lincoln), M. R. Banerjee and D. Medina. *J Nat Cancer Inst* 46(4):899-907, 1971.

The relationship between the frequency of cells in the proliferative pool during DNA synthesis and the carcinogenic efficiency of 3-methylcholanthrene during the progressive growth of D1 nodule outgrowth tissue following fat-pad transplantation was studied in mammary-tumor-virus-free outgrowths of BALB/c mice by means of thymidine labeling. As measured by ³H-thymidine incorporation, DNA synthesis in the outgrowths gradually increased and reached a peak 4 wk after fat-pad transplantation; the rise in DNA synthesis rate during the initial 3 wk was relatively

slow, and after 4 wk the incorporation of the labeled DNA precursor increased 150% over the value obtained at 1 wk after transplantation; this peak was followed by a consistent drop to 37% at 8 wk. The frequency of labeled alveolar epithelial cells showed a rise and peaked also at 4 wk after transplantation but was reduced at 5 wk and remained constant until the 8th wk. D1 nodule outgrowths in mice receiving 3-methylcholanthrene feedings at 3 and 5 wk after transplantation produced 56% and 67% tumors, resp., in 2 groups; however, later administration of the carcinogen resulted in a decreased incidence of tumor formation as well as a failure of tumors that did form to increase in size between feedings; this differed from observations in animals fed 3-methylcholanthrene at 3 and 5 wk where a 100% increase of outgrowth size occurred during the 2 feedings. Results suggest that an interaction does occur between methylcholanthrene and DNA.

803 CHROMOSOME STUDIES ON A TRANSPLANTABLE GRANULOCYTIC LEUKEMIA (CHLOROLEUKEMIA) OF RAT. (Jap.) Sakai, T. (Showa U. Sch. Med., Tokyo, Japan). *Acta Haemat Jap* 33(4):402-414, 1970.

A granulocytic leukemia of the chloroleukemia type induced by 3-methylcholanthrene in rats was found to have chromosome numbers of 37-44 with 80% of the tumor cells having 43 chromosomes. An extra-long telocentric and a small chromosome were observed in the stemline karyotypes; a distal part of an acrocentric element appeared to have been translocated to 1 of the number 2 acrocentric chromosomes resulting in the extra-long element, while the other part of the acrocentric together with the centromere formed the small element. Cells with 42 or 44 chromosomes, which were occasionally seen, were thought to have been formed by the non-disjunction of one of the number 14 chromosomes. The tumor was found to have infiltrated the femoral bone marrow of tumor-bearing rats; the ratio of tumor cells to bone marrow cells was 10% and increased rapidly after the tumor had attained a size of 20 g. Infiltration by tumor cells of the peritoneal cavity was also seen; in the peritoneal cavity the tumor developed as an ascites tumor in the 47th and 60th transplant generation.

804 THREAD-INDUCED EPIDERMIZATION IN THE UTERINE HORN OF MICE, AND THE INFLUENCE OF 20-METHYLCHOLANTHRENE. (E.) Graham, C.E. (Yerkes Reg. Primate Res. Ctr., Emory U., Atlanta, Ga.). *Oncology* 25(1):83-93, 1971.

The mode of origin of new stratified squamous epithelium in response to implantation of beeswax-impregnated thread into the uterine cornua of C₃H/HeJ mice at the age of 6 wk was studied by means of stereomicroscopy. In animals treated with carcinogen/beeswax impregnated thread, more than 90% developed early invasive lesions of the stratified epithelium of the cervical canal with an abrupt demarcation between the stratified and columnar epithelium; the mean level of the junctions in contact

with the thread was invariably displaced cranially, and in some instances extended the total length of the uterus. In animals implanted with beeswax-impregnated thread without carcinogen the mean cranial displacement of the junction was least, and an intermediate amount of epidermization occurred in animals treated with plain thread. The histological appearance of the original and newly formed epithelium after contact for 4 wk with beeswax and 3-methylcholanthrene threads had a somewhat disorganized appearance, lacked a prickle-cell layer, and the surface layers were neither flattened nor cornified but presented occasional areas of atrophy; upon serial section both control and carcinogen-treated cervixes demonstrated continuity of the new stratified epithelium with the main mass. It appears likely that squamous cell cervical carcinomas arise not from the columnar cells but from stratified epithelium.

1805 ALTERATION IN THE MICROSOMAL HEMOPROTEIN AND THE KINETICS OF 3,4-BENZOPYRENE HYDROXYLASE INDUCED BY 3-METHYLCHOLANTHRENE: TIME COURSE STUDY AND EFFECTS OF PUROMYCIN. (E.) Alvares, A. P. (Rockefeller U., New York, N. Y.), G. Schilling and R. Kuntzman. *Life Sci* 10(3):129-136, 1971.

A dose of 25 mg/kg of 3-methylcholanthrene (MC) dissolved in corn oil was administered by a single i.p. injection to male Sprague Dawley rats. Actinomycin D was administered i.p. 1 hr prior to and 5 hr after the administration of MC. At hourly intervals for 12 hr, rats received puromycin (20 mg/kg, i.p.); rats were killed 1 hr after the last dose. Three and 12 hr after administration of MC, increases occurred in both the V_{max} and the ratio of 455:430 nm peaks of the ethyl isocyanide difference spectra of microsomes with a concurrent decrease in the apparent K_m for the hydroxylation of 3,4-benzopyrene. Puromycin alone had no effect on the apparent K_m of the hydroxylase whereas MC caused a marked decrease. This decrease was prevented when MC administration was followed by hourly injections of puromycin. Similarly, the increase in V_{max} and in the ratio of the 455:430 nm peaks following administration of 3-methylcholanthrene was prevented when followed by injections of puromycin. Similar results were obtained when actinomycin D was substituted for puromycin.

1806 PULMONARY ADENOMATA INDUCED BY CARCINOGEN TREATMENT IN ORGAN CULTURE: INFLUENCE OF INCREASING AMOUNTS OF CARCINOGEN. (E.) Davies, R. F. (Tobacco Res. Council, Harrogate, England), I. R. Major and E. R. Aberdeen. *Brit J Cancer* 24(4):785-787, 1970.

The effects of increasing amounts of tobacco carcinogens on mouse lung cultured *in vitro* was studied in BALB/c mice. Explants examined immediately after treatment in culture whether exposed to carcinogen or not were normal in appearance. However, explants after inoculation into mice showed lymphoid hyperplasia which did not appear to be influenced by the carcinogen or the development of an adenoma. The percentage of

takes with adenomata ranged from 30% with 4.4 µg/ml 3-methylcholanthrene to 64% with 7.1 µg/ml 3-methylcholanthrene.

- 1807 ULTRASTRUCTURAL ANALYSIS OF RENAL MESENCHYMAL TUMOR INDUCED IN THE RAT BY DIMETHYLNITROSAMINE. (E.) Hard, G. C. (Med. Res. Counc. Lab., Carshalton, England) and W. H. Butler. *Cancer Res* 31(3):348-365, 1971.

The predominant cell type in renal mesenchymal tumors induced in rats by injections of dimethylnitrosamine was spindle shaped, but stellate cells were frequent in less cellular areas of the stroma. Tumor cells also differentiated into pericytes, endothelial cells, vascular smooth muscle fiber cells, and rhabdomyoblasts. In the spindle-shaped cells, granular endoplasmic reticulum was conspicuous in the cytoplasm, and ribosomes were numerous. Tumor cells frequently formed small aggregates enclosing a cleft-like lumen; the formation of these groups resembled capillary formation. Tumor cells tended to group together in areas of low cell-density as well as in areas of high cell-density. Enclosed lumina occasionally contained red cells. The tumor areas were supplied with vascular channels which were lined with endothelial cells indistinguishable from adjacent free tumor cells, showing that the vascular-lining cells were an integral part of the tumor. Epithelial tissue consisted of isolated preexisting tubules and glomeruli; some tubules were stimulated to hyperplastic proliferation. Mesenchymal tumor cells could not be shown to be the origin of the epithelial elements. Apparently, the renal mesenchymal tumor should be regarded as a vascular tumor arising from mesenchymal cells in the renal cortical interstitial space.

- 1808 ULTRASTRUCTURAL STUDY OF THE DEVELOPMENT OF INTERSTITIAL LESIONS LEADING TO MESENCHYMAL NEOPLASIA INDUCED IN THE RAT RENAL CORTEX BY DIMETHYLNITROSAMINE (E.) Hard, G. C. (Med. Res. Counc. Lab., Carshalton, England) and W. H. Butler. *Cancer Res* 31(3):337-347, 1971.

Male rats were given i.p. injections of 30, 50 or 60 mg/kg dimethylnitrosamine (DMN) and killed after periods ranging from 1 day to 20 wk later; kidney sections were prepared for electron microscopic examination. Intracellular damage was visible in interstitial fibroblasts in the vicinity of glomeruli within 1 day after injection of DMN; intracellular changes involved accumulation of lipid droplets, formation of myelin figures, disorganization of nucleoli and dilation of the rough endoplasmic reticulum in some cells. By 4 days postinjection, autophagic vacuoles were seen in some cells. Within 2-4 days, some periglomerular cortical fibrocytes and capillary endothelial cells were stimulated into division. Monocyte infiltration through breaks in capillary walls was frequent. An interstitial mononuclear inflammatory reaction with the macrophage as the dominant cell was observed, reaching a peak by 7 days postinjection. By 3 wk postinjection and thereafter, some hypercellular foci persisted, and the lymphocyte was the dominant cell form. By 12 wk,

there was a marked reduction of immunological cells, and persisting lesions consisted chiefly of aggregation of fibroblast-like cells similar to spindle or stellate tumor cells. By 20 wk postinjection, mesenchymal tumors were seen to be well developed and showed wide cellular differentiation. All changes were most pronounced in cells from rats given 60 or 50 mg DMN; in animals given 30 mg DMN, lesions were milder and persisted in only about 30% of cases.

- 1809 ULTRASTRUCTURAL ASPECTS OF RENAL ADENOCARCINOMA INDUCED IN THE RAT BY DIMETHYLNITROSAMINE. (E.) Hard, G. C. (Med. Res. Counc. Lab., Carshalton, England) and W. H. Butler. *Cancer Res* 31(3):366-372, 1971.

Renal tumors were induced in rats by a single i.p. injection of 50 mg/kg dimethylnitrosamine, and examined under the electron microscope. Cells within a single tumor showed widely varying degrees of cytoplasmic differentiation; in well-differentiated cells, mitochondria of circular or elongate outline were common, while in more poorly-differentiated cells the mitochondria were usually of irregular shape. The cells of the adenocarcinomas developed abnormal clusters of brush border, usually at the junction of closely apposed cells. Tumor cells also showed hypertrophied nucleoli and Golgi apparatus. These features of dimethylnitrosamine-induced adenocarcinomas appeared to confirm the hypothesis that these tumors arise from proximal convoluted tubules.

- 1810 RENAL TUMORS INDUCED IN RATS BY DIMETHYLNITROSAMINE: ESPECIALLY ON ITS HISTOGENESIS AND GROWTH PATTERN. (Jap.) Kimura, M. (Sch. Med. Tokushima U., Japan). *Shikoku Acta Med* 26(5):481-489, 1970.

Renal tumors were induced in newborn and adult rats placed on 3 regimens of dimethylnitrosamine (DMN) administration: 1 group of adults was fed a diet containing 200 ppm of DMN for 2 months; a second group consisted of newborn rats which were given a single s.c. injection of 100 µg DMN and 50 ppm of DMN in drinking water; a third group of newborns was given a single s.c. injection of 100 µg DMN. Nonepithelial tumors of the kidney developed in all 3 experimental groups; epithelial tumors developed only in animals in the first group. Nonepithelial tumors were composed chiefly of undifferentiated mesenchymal tumor cells. Tumor nodules composed of spindle-shaped tumor cells were seen at the corticomedullary junction in sections of early kidney lesions. These tumors may have arisen from interstitial cells of the corticomedullary junction to fuse and enlarge. Epithelial renal tumors were adenomas or adenocarcinomas.

- 1811 STUDIES ON THE TRANSPLACENTAL TERATOGENIC, CARCINOGENIC, AND MUTAGENIC EFFECT OF DIMETHYLNITROSAMINE AFTER ORAL ADMINISTRATION TO RAT.

(Ger.) Sydow, G. (German Acad. Sci., Berlin). *Arch Geschwulstforsch* 36(4):331-334, 1970.

Male and female rats aged 5 months were given 1 mg diethylnitrosamine (DENA) per animal in drinking water daily. After 35 days (series A), 50 days (series B) and 60 days (series C), 20 males and females of each group were mated, at which time and until parturition, the animals continued on DENA. The newborn were kept until they died at which time they were examined for tumors. The young of series A, were mated at 5 months without any further treatment with carcinogen and followed for 4 generations or observation of the mutagenic effect of the carcinogen. The oral ingestion of the DENA had no effect on the conception and fertility of the animals; no teratogenic, mutagenic or carcinogenic effects were observed in newborn rats. The life span of the offspring of the treated animals were shortened by about 1 year due to pneumonia or to degenerative inflammation and necrosis of the liver. These pathological changes were not observed in the following generation.

1812 DIETHYLNITROSAMINE-INDUCED RENAL TUMORS IN PARTIALLY HEPATECTOMIZED RATS. (Ger.) Habes, H. (Path. Inst. U. Munich, Germany), R. Harenstein and J. Gminder. *Naturwissenschaften* 58(2):102-103, 1971.

Three groups of partially hepatectomized rats were given a single i.p. injection of 80 mg/kg of diethylnitrosamine (DENA) at 4, 16 or 24 hr after surgery. Six hundred days later, mortalities with renal tumors were 78%, 59% and 20%, resp., for the 3 groups; mortalities increased to 83%, 65% and 53%, resp., by 900 days after surgery. Massive bilateral tumors up to 7 cm in diameter had developed and were comprised of adenomas, adenocarcinomas and anaplastic tumors. However, no hepatic tumors were found. It is postulated that because of the hepatic dysfunction due to partial hepatectomy, the formation of the proximate carcinogens from DENA in the liver was reduced, so that hepatic tumors did not develop; for similar reasons, the biological half-life of the carcinogen increased. As a result there may have been a greater possibility that a critical level of carcinogen required for production of tumors in the kidney was reached.

1813 CARCINOGENIC ACTIVITY OF ALIPHATIC NITROSAMINES VIA THE MOTHER'S MILK IN THE OFFSPRING OF SYRIAN GOLDEN HAMSTERS. (E.) Mohr, U. (Med. Coll. Hannover, Germany) and J. Althoff. *Proc Soc Exp Biol Med* 136(3):1007-1009, 1971.

Female hamsters were given s.c. injections of 5, 10 or 20 mg/kg diethylnitrosamine (DEN) 1-30 days following delivery of litters; other lactating hamsters were given 300, 600 or 1200 mg/kg of dibutylnitrosamine (DBN). Eleven of 15 DEN-treated mothers developed tracheal papillomas and 6 of 15 DEN-treated mothers developed nasal cavity tumors. Among the offspring of DEN-treated hamsters, 12 of 23 developed tracheal papillomas and 1 of 23 developed nasal cavity tumors. Eleven of 15 DBN-treated mothers

developed tracheal papillomas and none of the 15 DBN-treated mothers developed nasal cavity tumors. Among the offspring of DBN-treated hamsters, 5 of 18 developed tracheal papillomas and none of the 18 offspring developed nasal cavity tumors. The latent period for development of tumors in lactating mothers was 8 wk for DEN-treated hamsters and 24 wk for DBN-treated hamsters. The results appeared to suggest that a carcinogenic agent associated with aliphatic nitrosamines could be transmitted from mothers to offspring via milk.

1814 THE ACTIVITY OF GLUCOSE-6-PHOSPHATASE AT DIFFERENT STAGES OF LIVER CANCER DEVELOPMENT: THE EFFECT OF SOME INDUCTORS. (Rus.) Isok, M. E. (Inst. Exp. and Clin. Med., Tallin, U.S.S.R.) and L. E. Teras. *Vop Med Khim* 17(1):40-46, 1971.

The effect of inducing agents such as hydrocortisone, insulin and glucose on glucose-6-phosphatase (G-6-Pase) activity in the liver during diethylnitrosamine (DENA) hepatocarcinogenesis in rabbits and rats was investigated. DENA was given to male rabbits (2.5 mg/kg p.o.) and to white male rats (2.5 or 5 mg/kg for 8 months. Hydrocortisone acetate (5mg/100 g) was given twice daily i.m. for 7 days, insulin (4 U/100 g) s.c. for 2 days and glucose (6.6 ml of a 5% solution) i.p. 6 times within 48 hr at different times during the experimental period. A decrease in G-6-Pase activity (from 1000 to 820 mg P/g tissue) was observed in rabbit liver in the 2nd month of DENA treatment; this activity decreased to 42% during the 5th month and to 30% of the control levels during the 6th, 7th and 8th months of DENA administration. Cessation of carcinogen administration led to a sudden decrease of G-6-Pase to 10% of the normal levels during the 9th month of the experimental period. The rats in the 5 mg/kg DENA-treated group showed a decreased G-6-Pase activity before the occurrence of neoplastic foci; G-6-Pase activity was 50% of control levels at the end of the 8th month of treatment. A 30% decrease of G-6-Pase occurred in the 2.5 mg/kg DENA-treated rats at the end of the 8th month of the experimental period, when hepatomas were macroscopically well defined. Hydrocortisone induced a 40% increase in G-6-Pase activity in both control and DENA-treated animals after 3 months of treatment; it produced no effects starting from the 5th month of treatment although hepatomas occurred only during the 8th month of DENA treatment. The loss of liver cell susceptibility to hydrocortisone was thought to be a pretumorous condition. Minor repression of G-6-Pase (6-10%) induced by insulin was seen in both control and DENA-treated animals during the first 5 months and a slight increase of G-6-Pase occurred after 8 months of carcinogen administration. Glucose had no repressive effects on G-6-Pase during the last period of hepatocarcinogenesis. A loss of liver cell susceptibility towards hormonal alterations was ascertained during the late states of DENA hepatocarcinogenesis.

1815 THE INFLUENCE OF IMMUNOSUPPRESSIVE DRUGS ON CANCERIZATION OF RAT LIVER BY DIETHYLNITROSAMINE AND ON INDUCTION OF FIBROSARCOMA BY 3,4-

BENZPYRENE. (Ger.) Schmähl, D. (German Cancer Res. Ctr., Heidelberg, Germany), R. Wagner and H. R. Scherf. *Arzneimittelforschung* 21(3):403-404, 1971.

Male Sprague-Dawley rats, in whom liver cancerization and fibrosarcoma were chemically induced by diethylnitrosamine (3 mg/kg/day, p.o.) and benzo(a)-pyrene (6 mg/rat, s.c.), resp., were treated at the same time with hydrocortisone (50 mg/kg/wk, p.o.); another group was given cyclophosphamide (13 mg/kg/wk, i.v.) with carcinogen to determine the effects of these immunosuppressors upon tumor production and induction time. A separate group of rats received cyclophosphamide only as control. On the basis of systematic palpation for tumor formation throughout the rats' lifespan no significant effects of these immunosuppressors could be shown on the following parameters: tumor production, induction time, growth rate, and histology of tumors.

1816 THE TRANSPLACENTAL CARCINOGENIC EFFECTS OF N-NITROSODIETHYLAMINE IN MICE. (Rus.)

Likhachev, A. Ya. (N. N. Petrov Res. Inst. Oncol., Leningrad, U.S.S.R.). *Vop Onkol* 17(1):45-50, 1971.

The incidence and morphology of tumors which developed in mice from mothers exposed to diethylnitrosamine (DENA) in mice were investigated. Forty-nine white randbred or C3HA pregnant mice were given DENA (120 mg/kg) 24-48 hr prior to delivery; the offspring were kept with their mothers for 8-10 wk. The incidence of tumors was 76% in the randbred and 82% in the C3HA offspring; spontaneous tumor incidence was 9% in the randbred and 1% in the C3HA controls. The first neoplasm (a squamous cell epithelioma of the esophagus) was noticed in a mouse that died 333 days after transplacental exposure to DENA. Lung tumors were most frequent (31/41 of the randbred and 9/11 of the C3HA mice) and appeared to be papillary, tubular or trabecular adenomas; giant tumors occurred in a few cases and had morphologically detectable malignant foci. Single or multiple tumors developed in 6/41 randbred and 2/11 C3HA mice and appeared to be adenomas of hepatocellular origin sometimes revealing polymorphous structures along with lipid and protein dystrophy. The incidence of leukemia (3/41) in the randbred mice and mammary gland tumors (1/41) was similar in the randbred controls and treated animals; no leukemias occurred in the C3HA offspring. The average latency period was 587 days.

1817 FINE STRUCTURE ALTERATION OF RAT LIVER INDUCED BY NITROSOHEXAMETHYLENAMINE. (E.)

Kim, C. S. (Yonsei U. Coll. Med., Seoul, Korea) and M. Greenblatt. *Yonsei Med J* 11(1):31-41, 1970.

Female rats were given 4 mg of nitrosohexamethylenamine (NHM) in drinking water 5 days per wk for 10 days or 5-22 wk; total doses of NHM ranged from 40-440 mg. Periportal hyperplasia, occasional mitosis and doubly nucleated cells were seen in the liver by light microscopy. In animals exposed to NHM for 10

days and for 5 wk, electron microscopy showed dilated endoplasmic reticulum and Golgi apparatus and an increased number of lysosomes. After 11 wk of NHM feeding, nucleoli of liver cells were enlarged but not segregated and the smooth endoplasmic reticulum showed increased vesiculation. After 14 wk nuclei and nucleoli were markedly enlarged, and after 22 wk there was prominent hyperplasia of the smooth endoplasmic reticulum and increased glycogen particles. Bile canaliculi were dilated and endothelial cells were swollen; an increased number of Kupffer cells were also seen in NHM-fed rats.

1818 GLYCOGEN AND ENDOPLASMIC RETICULUM OF THE LIVER CELL AFTER HIGH DOSES OF THE CARCINOGEN N-NITROSOMORPHOLINE. (Ger.) Theodossiou, A. (Path. Inst. U. Würzburg, Germany), P. Bannasch and W. Reuss. *Virchow Arch Zellpath* 7(2-3):126-146, 1971.

Rats given 50 mg% N-nitrosomorpholine (NNM) in drinking water developed changes in glycogen, endoplasmic reticulum and ribosomes in liver cells, as observed by electron microscopy. All hepatocytes manifested pronounced losses of glycogen, and the endoplasmic reticulum showed loss of organization and proliferation. Some ribosomal reduction and some ribosomal enhancement were seen during maintenance on the carcinogenic regimen. Proliferating endoplasmic reticulum often transformed into an atypical granular condition. Coagulation necrosis was seen in ribosome-deficient cells, while ribosome-rich cells showed high incidences of abnormal mitoses. Ribosomal enhancement, hepatocellular glycogen loss, and increased mitosis reversed within 5 wk after cessation of NNM administration. These changes were not considered to be precancerous, but were changes in response to acute toxic effects.

1819 STUDIES *IN VITRO* ON A POSSIBLE FORMATION OF CANCEROGENIC NITROSAMIDES. (Ger.)

Sander, J. (Hyg. Inst. U. Tübingen, Germany), G. Bürkle, L. Flohe and B. Aeikens. *Arzneimittelforschung* 21(3):411-414, 1971.

The formation of cancerogenic nitrosamides under simulated physiological conditions was investigated as a possible cause of gastric cancer. The formation of nitrosamides from alkylamides at low pH's was determined polarographically. Degradation of methyl and ethyl nitrosourea's occurred in strong acid solutions, the half life being approximately 1 hr at pH 1.0. Methyl and ethyl urethan were nitrosated *in vitro* with progressively higher yields at decreasing pH values, although at these low pH values the nitroso-binding was decreased. Rapidly formed nitroso derivatives were obtained from the incubation of methyl and ethyl urea with nitrite. N-Methylacetamide was not nitrosated to any measurable extent under these conditions. Pilot studies in nitroso derivative formation in animals *in vivo*, have thus far produced negative results in tumor induction.

- 1820 EVIDENCE OF FORMATION OF N-METHYL-N-NITROSOUREA IN RATS GIVEN N-METHYLUREA AND SODIUM NITRITE. (E.) Montesano, R. (Middlesex Hosp Med. Sch., London, England) and P. N. Magee. *Int Cancer* 7(2):249-255, 1971.

Evidence was found for the formation of N(¹⁴C)-methyl-N-nitrosourea in the stomach of rats from nitrosation of N(¹⁴C)-methylurea; the presence of labeled 7-methylguanine was detected in DNA and RNA of several organs of rats administered N(¹⁴C)-methylurea and sodium nitrite. Samples of N(¹⁴C)-methylurea (250 µC, 8.2 mg/ml) were mixed with sodium nitrite solution and administered by stomach tube to rats; 5 hr later the rats were killed and nucleic acids of stomach, liver and small intestine were assayed for incorporation of labeled N(¹⁴C)-methylurea. In rats given N(¹⁴C)-methylurea alone radioactivity was not incorporated into 7-methylguanine of nucleic acids of the stomach tissues. When N(¹⁴C)-methylurea and sodium nitrite were administered simultaneously, incorporation of radioactive label into nucleic acids was much higher than in the N(¹⁴C)-methylurea-treated rats. Ion-exchange chromatograms of hydrolysates of stomach, liver and small intestine nucleic acids showed a radioactive peak corresponding to the altered base 7-methylguanine in rats treated with both N(¹⁴C)-methylurea and sodium nitrite. Apparently the carcinogen N-methyl-N-nitrosourea is formed in the stomach as a result of nitrosation of the corresponding secondary amide.

- 1821 MORPHOLOGICAL STUDIES OF RAT BRAIN TUMORS INDUCED BY N-NITROSOMETHYLUREA. (E.) Schmidek, H.H. (Massachusetts Gen. Hosp., Boston), L. Nielsen, A.L. Schiller and J. Messer. *J Neurosurg* 33(3):335-340, 1971.

Experimental glial tumors induced by injection of N-nitrosomethylurea (5 mg/kg/wk) in Wistar and C.D. Fisher rats were studied for morphological characteristics. Autopsy showed primary brain tumors in 2 of 58 animals surviving the 36 weekly injections, and 11 of these were successfully propagated in both in vivo tissue and tissue cultures and maintained over at least 2 generations. Three low-grade astrocytomas (stable over at least 6 passages), 4 high-grade astrocytomas (stable over 2-14 generations), 2 spindle-cell tumors (stable for 2-4 passages), and mixed gliomas (which evolved into a high-grade astrocytoma and a plasmacytoma and became stable) developed between 17-43 wk after termination of injections. Low-grade astrocytomas revealed indistinct cytoplasmic borders with homogeneous diffuse nuclear chromatin, while high-grade astrocytomas exhibited moderate pleomorphism and stellate areas of necrosis bordered by palisading tumor cells. The predominant pattern in the mixed gliomas was that of numerous elongated, ovoid cells with spindle-shaped nuclei and indistinct cytoplasm and lack of necrosis. Serial subcutaneous transplants provided a stable cell line of low and high-grade astrocytomas for experimental models.

- 1822 BLOOD-BRAIN BARRIER FOR THYMIDINE IN EXPERIMENTALLY PRODUCED TUMORS OF THE CENTRAL NERVOUS SYSTEM OF THE RAT. (Ger.) Citoler, P. (Path. Inst. U. Bonn, Germany), H. J. Drechsler and C. Thomas. *Virchow Arch Zellpath* 7(2-3):260-262, 1971.

Rats in whom tumors of the nervous system had been induced by methylnitrosourea (5 mg/kg/day) were sacrificed 1 hr after i.p. injection of 250 µC of ³H-thymidine, and the intensity of isotope labeling was measured autoradiographically in the cells of the chorioid plexus, gastric mucosa, and of various neurogenic tumors. Cells of the CNS tumors invariably showed clearly lower levels of radioisotope than did those peripheral to the blood-brain barrier including peripheral normal tissues. Some gliomas and all adventitial sarcomas showed areas of many mitoses but without tritium labeling. A varying relative permeability of blood-brain barrier for different tumors is offered as an explanation of these findings.

- 1823 EXPERIMENTALLY INDUCED TUMORS IN GLANDULAR STOMACH IN GUINEA-PIG AND RAT. (Ger.) Bücheler, J. (Path. Inst. U. Freiburg, Germany) and C. Thomas. *Beitr Path* 124(2):194-209, 1971.

Guinea pigs and rats were given methylnitrosourea (MNU) and methylnitrosourea (MNH) in drinking water (2.5 mg/kg) daily. Tumors developed in the stomach and/or pancreas of the guinea pigs and in the rats' glandular stomach after 800 days and 740 days, resp. Of 25 MNH treated guinea pigs developing 12 malignant tumors, 7 tumors were in the region of the stomach and pancreas. MNU produced 26 tumors in 38 guinea pigs, 25 of which were found in the stomach-pancreas region. The types of tumors found were sarcomas (2) and carcinomas (30). Solid, alveolar or scirrhous tumors were found only on the stomach wall; in 3 cases the tumor developed at the site of a chronic gastric ulcer. The pancreas was involved in 5 cases which showed no malignant involvement of the stomach. Glandular stomach tumors developed in 16 rats given acetylmethylnitrosourea (AMNH, in 2 and 4 mg/kg); latency for tumor induction by AMNH was 500 days and 100% of treated rats developed tumors. Two glandular stomach tumors were sarcomas and 16 were adenocarcinomas.

- 1824 ESTABLISHMENT AND SOME CHARACTERISTICS OF NEW TRANSPLANTABLE ASCITES TUMORS PRODUCED BY RAT LIVER CELLS TRANSFORMED IN CULTURE WITH 4-NITROQUINOLINE-1-OXIDE. (E.) Namba, M. (Okayama U. Med. Sch., Japan) and J. Sato. *Gann* 61(6):583-587, 1970.

Rat liver tissue cells were transformed *in vitro* by treatment with 4-nitroquinoline-1-oxide (10⁻⁶M for 20 times over 108 days); the transformed cells produced 2 transplantable lines of ascites tumors when inoculated into rats. The solid tumors were poorly differentiated, and liver cell carcinomas metastasized to lymph nodes and lungs. The tumor lines have been

passaged 30 and 36 times; tumor take occurred in 100% of rats in all generations. The inoculation of 700 cells of one tumor line or 460 cells of the other line killed host animals with 3 months. Tumor cells in both lines lacked glucose-6-phosphatase and glycogen. Sensitivity of one of the tumor cell lines to 4-nitroquinoline-1-oxide was compared with the sensitivity of cells of a hepatoma (AH-66) induced by 4-dimethylaminoazobenzene. The median survival time of rats injected with ascites tumor cells treated with $10^{-4.5}M$ of 4-nitroquinoline-1-oxide was 29 days compared with 21 days for tumor cells not treated with 4-nitroquinoline-1-oxide; animals injected with untreated AH-66 tumor cells survived 12 days compared to 17 days for those injected with cells treated with $10^{-4.5}M$ 4-nitroquinoline-1-oxide. These results indicate that the 4-nitroquinoline-1-oxide-transformed cells did not acquire resistance to the chemical carcinogen.

1825 A PROPOSED MODEL OF THE INTERACTION OF 4-NITROQUINOLINE-1-OXIDE WITH DNA.

(E.) Paul, J. S. (U. Texas Southwestern Med. Sch., Dallas), P. O'B. Montgomery, Jr. and J. B. Louis. *Cancer Res* 31(4):413-419, 1971.

Extended Hückel molecular orbital calculations were made for twenty-seven 4-nitroquinoline-1-oxides (4-NQO) of known carcinogenicity. The following strength of complex formation and presumably the following order of decreasing carcinogenicity were predicted according to the Mulliken population: 6-chloro-4-NQO > 4-NQO > 6-carboxy-4-NQO > 4,6-dinitroquinoline-1-oxide > 4-nitropyridine-1-oxide. Noncarcinogenicity or reduced carcinogenicity was due to the absence of the 4-nitro group or a 1-oxide group or to the presence of bulky substituents in the 2 or 3 position on the quinoline ring. Based upon the experimental evidence and the molecular orbital calculations a possible model of complex formation was formulated hypothesizing a 2-point attachment which involved hydrogen bonding between the oxygen of the 1-oxide group of 4-NQO and the hydrogen of the deoxyguanosine amino group and the transfer of a nonbinding electron from the deoxyribose group to a singly occupied orbital of the nitrogen in the 4-nitro group.

1826 RELATIONSHIP BETWEEN CARCINOGENICITY AND ELECTRONIC STRUCTURE OF MONONITROQUINOLINES.

Kurihara, T. (Lab. Organic Chem., Josai U., Saitama, Japan), H. Ichimura, T. Igaki and A. Ohta. *Chem Pharm Bull* 19(1):37-40, 1971.

The superdelocalizability of 7 mononitroquinoline isomers relative to their carcinogenic properties were investigated by the Hückel method. The carcinogenic isomers, 2- and 4-nitroquinolines, had superdelocalizability values of 1.479 and 1.579, resp., whereas the noncarcinogenic 3-, 5-, 6-, 7-, and 8-nitro isomers had values of 0.173-0.440. These values were considered to be qualitative and it is not clear whether or not a linear relationship exists between carcinogenesis and superdelocalizability values. The reaction indices of several 2- and 4-nitroquinolines with a halogen, methyl or nitro

substituent in the 6-, 8-, and 4- or 2-positions, resp., were given; all had superdelocalizability values greater than 1.00, but biological testing for carcinogenic activity has not yet been done on these compounds.

1827 COMPARATIVE CARCINOGENICITY OF 4-HYDROXY-AMINOQUINOLINE-1-OXIDE AND ITS DIACETYL DERIVATIVES IN MICE AND RATS. (E.) Enomoto, M. (Inst. Med. Sci., U. Tokyo, Japan), E. C. Miller and J. A. Miller. *Proc Soc Exp Biol Med* 136(4):1206-1210, 1971.

Female mice of the CD-1 strain and male rats were treated either topically on shaved dorsal skin or by s.c. injection with 4-hydroxyaminoquinoline-1-oxide (HQ) or its 0,0'-diacetyl derivative (DAHQ). Topical application of 12 μ moles of HQ or DAHQ to mice produced papillomas in up to 50% of mice after latencies of 3-4 months. By 9-12 months after treatment, some squamous cell carcinomas had developed. Both compounds induced sarcomas in 25% of mice given 5 injections of 3.2 μ moles; mice given 10-15 injections of either agent developed sarcomas in 31-57% of cases. Latencies for sarcoma induction in these mice were 4-5 months after the higher number of injections and 6-8 months after the lower number of injections. A single injection of 1 mg of HQ in rats induced fibro- and myosarcomas in 70% of animals within 16 months while equivalent injection of DAHQ induced sarcomas in only 4 of 36 rats given 3 injections. The reason for the comparatively slight carcinogenicity of DAHQ in rats remains obscure.

1828 LATENT MEIOTIC ANOMALIES RELATED TO AN ANCESTRAL EXPOSURE TO A MUTAGENIC AGENT.

(E.) Lavappa, K. S. (Harvard Med. Sch., Boston, Mass.) and G. Yerganian. *Science* 172(3979):171-174, 1971.

Adult male Armenian hamsters were given i.p. injections of ethyl methanesulfonate (100 mg/kg) and bred to normal females. The F_1 generation included 15 males, 2 of which showed chromosomal translocation. These hamsters were bred, and their male offspring were given an i.p. dose of 100 mg/kg urethan; analysis of meiotic bivalents at diakinesis was performed. Urethan produced no chromosomal abnormalities in hamsters grand-sired by untreated animals. However meiotic cells of animals with ethyl methanesulfonate treated grand-sires exhibited 2 distinct forms of cytological abnormalities: association of bivalent end-to-end, leading to a reduction in the number of paired elements in diakinesis; and site-specific deletions of the X chromosome at the junction of positive and negative heteropachytic segments of the long arm. X chromosome deletions and bivalent associations were most frequently observed 6 and 8 days resp., after urethan treatment. Apparently, these anomalies were maintained in a latent state for 2 generations after ethyl methanesulfonate treatment and were made overt by urethan treatment.

- 29 THE ROLE OF REPEATED ADMINISTRATION OF SUCKLING MICE WITH URETHAN ON CARCINOGENESIS. (E.) Matsuyama, M. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan) and H. Suzuki. *Nagoya Med J* (2):105-111, 1970.

7 days of age, mice of strains AKR/JMs and dd/I were given the first of a series of 1-4 s.c. injections of 1 mg/kg of urethan. In AKR/JMs mice, malignant thymic lymphoma developed to a greater extent in mice given multiple doses; by 200 days after birth, 100% of the mice given 4 injections of urethan had died with thymic lymphoma, compared with 60% of the mice given 3 injections, 30% of the mice given 2 injections, 20% of the mice given a single injection, and none of the mice given 4 saline injections (controls). In mice of this strain, spleen, liver, lymph nodes, kidneys and ovaries were also grossly affected. Mice of the dd/I strain, female mice given 2, 3 or 4 injections of urethan developed lymphoma in 75, 83 and 71% of cases, resp., and mice given 1 injection developed lymphoma in 32% of cases. Leukemogenesis was less pronounced in males, but the dose-response observed for females and for AKR/JMs mice was similar. Lung cancer was also seen in dd/I mice; mice given 1 or 3 doses of urethan developed fewer carcinomas than those given 3 or 4 doses. Half the carcinomas induced in dd/I mice were anaplastic.

- 30 A MASSIVE LIPOMA IN A PATIENT RECEIVING CHLORPROPAMIDE THERAPY. (E.) Garfinkel, A. (St. Mary's Hosp., London, England). *Postgrad Med J* 47(544):137-138, 1971.

A 60-yr-old Pakistani male developed a lipoma on his upper back over a period of 16 years which eventually attained dimensions of 30 cm x 24 cm x 20 cm and a weight of more than 5 kg. He had been taking chlorpropamide for a suspected diabetic condition for 16 years. The patient may have had a small lipoma which grew to its final massive size as a result of the chlorpropamide regimen; the tumor may have incorporated glucose into its metabolic pathways more avidly than did the rest of his body due to the increased serum insulin levels brought about by chlorpropamide.

- 31 ADENOCARCINOMA OF THE VAGINA: ASSOCIATION OF MATERNAL STILBESTROL THERAPY WITH TUMOR APPEARANCE IN YOUNG WOMEN. (E.) Herbst, A. L. (Vincent Mem. Hosp., Boston, Mass.), H. Ulfelder and D. Poskanzer. *New Eng J Med* 284(16):878-881, 1971.

Eight cases of carcinoma of the vagina arising in young women 14-22-yr-old were investigated by examining conditions surrounding their births and the births of women of similar ages born in the same hospitals under similar conditions (controls). The lesions included clear cell and endometrial adenocarcinomas. Comparison of patients with matched controls indicated that there was a highly significant correlation between treatment of their mothers with diethylstilbestrol during pregnancy and subsequent development of vaginal carcinoma; 7 of the 8 patients' mothers had taken stilbestrol during preg-

nancy. Maternal bleeding during the pregnancy which produced the carcinoma patient was also correlated with development of carcinoma to a significant degree. Maternal age at time of pregnancy, maternal smoking, intrauterine X-ray exposure, and breast feeding were apparently not related to development of vaginal carcinoma.

- 1832 EFFECTS OF DEPO-MEDROXYPROGESTERONE ACETATE AS A CONTRACEPTIVE AGENT. (E.) Powell, L. C., Jr. (U. Texas Med. Branch, Galveston) and R. J. Seymour. *Amer J Obstet Gynec* 110(1):36-41, 1971.

Of 1,107 women receiving depo-medroxyprogesterone acetate (DMPA) as an oral contraceptive, 23 showed suspicious or positively abnormal cytological cervical smears; this incidence yielded a rate of 21 abnormal cytological smears/1000 patients, which was not thought to be above expectation for the patient group involved -- Negroes of an older age group and high parity. Of 82 patients undergoing histological examination of the cervix, there were 11 cases of dysplasia and 11 instances of carcinoma *in situ*. There were no cases of invasive carcinoma or other genital malignancy. Among children born to women on DMPA after discontinuation of the contraceptive, there was a single instance of hemangioma of the face.

- 1833 THE ROLE OF SMOKING IN THE ETIOLOGY OF LUNG CANCER: EXPERIMENTAL INVESTIGATIONS. (Rus.) Krasnyanskaya, P. N. (Res. Inst. Oncol., Tiflis, U.S.S.R.). *Vop Onkol* 17(1):59-62, 1971.

The effects of smoking Georgian tobacco on the respiratory system in rabbits under conditions comparable to human smoking were investigated. Two experimental groups were used: I) 69 rabbits were exposed to smoking of 9 cigarettes daily (which corresponded to heavy smokers) for 4 yr; IIa) 10 rabbits were given pure benz(a)pyrene (15-20 mg intratracheally single dose) and exposed to smoking 9 cigarettes daily starting 12 days later for 1.5 yr; IIb) 16 rabbits received only benz(a)pyrene as above. Inflammatory processes were seen in group I at the bronchial and bronchiolar level within the first 3 months of the experiment. Irregular hyperplasia of the bronchial and bronchiolar epithelium occurred towards the end of the 1st yr when the animals had smoked 1500-2000 cigarettes. Focal proliferation in the lungs was seen after 1-4 yr when the rabbits had been exposed to 3300-8800 cigarettes. Papillomatous, polypous or adenomatous growth was observed in certain regions of the lung. Combined benz(a)pyrene and smoking exposure (group IIa) induced focal proliferations within 1-1½ yr. Regions of epithelial proliferation could be noticed in the lining of the tracheal epithelium, and no alterations were seen in the nasal epithelium. Cigarette smoking is concluded to be a weak carcinogenic factor for the lung tissue. Group IIa rabbits developed inflammatory changes during the first 3 months; some chronic alterations which developed later were the replacement of normal lung tissue by granular tissue followed by connective tissue.

- 1834 LUNG AND TOBACCO. (Fr.) Fournier, E.
(Hosp. Fernand Vidal, Paris, France) and
P. Zivy. *Poumon Coeur* 26(9):1109-1125, 1970.

The relationship of smoking to various respiratory diseases was studied with particular attention to idiopathic spontaneous pneumothorax. This condition usually appearing after the age of 25 yr, was often linked with smoking and was justified by a statistical analysis which showed a positive correlation between the incidence of this condition and the cigarette consumption of the patient. Among patients with an idiopathic spontaneous pneumothorax condition 36-45-yr-old, 80% smoked more than 15 cigarettes per day while in an age-matched group of healthy subjects, 35% smoked more than 15 cigarettes per day. Various lesions in the lungs were grouped under the diagnosis of "tobacco lung", which is described as a chronic toxic condition with discrete pneumoconiosis, where chronic bronchitis, sclerosis, and bullous emphysema predominated. Smoking apparently provokes the development of the bulla in this condition. Such conditions may lead to fatal consequences either through respiratory insufficiency or through cancerization.

- 1835 LEUKOCYTOSIS DURING LITHIUM TREATMENT. (E.)
Murphy, D. L. (Natl. Inst. Mental Hlth.,
Natl. Inst. Hlth., Bethesda, Md.), F. K. Goodwin and
W. E. Bunney. *Amer J Psychiat* 127(11):1559-1561,
1971.

Circulating leukocyte counts were found to be elevated in 8 manic and 20 depressed psychiatric patients undergoing a course of lithium therapy. Doses of lithium ranged from 1.2-1.8 gm/day, and serum lithium levels in the patients ranged from 0.85-1.30

mEq/l. The increase in venous blood leukocytes in 28 patients averaged 3,600 cells for manic patients and 1,900 cells for depressed patients. Some increase in leukocyte counts was apparent in most patients by the 5th day of lithium administration. During lithium therapy, all 8 of the manic patients but only one of the depressed patients had mean leukocyte counts of over 10,000/mm³; counts exceeded this value in 3 of the manic patients prior to lithium treatments. Leukocyte counts returned to pre-lithium levels within 1 wk after discontinuation of lithium.

PHYSICAL CARCINOGENESIS

38 VIRUS ASSOCIATION WITH ^{90}Sr INDUCED LEUKEMIA OF MINIATURE SWINE. (E.) Frazier, E. (Battelle Mem. Inst., Pacific Northwest Lab., Richland, Wash.), R. N. Ushijima and E. B. Howard. *Bibl Haemat* 36:440-445, 1970.

Preparations from lymph nodes, spleen, kidney, liver and blood plasma of swine in which leukemia was induced by chronic feeding with ^{90}Sr were found to contain virus particles similar in morphology to porcine leukemia virus. In sub-cultures of kidney tissue from leukemic swine, cells appeared to be transformed and harbored C-type viral particles. Primary cell cultures prepared from tissues of leukemic swine showed nuclear inclusions like those found in adenovirus-infected cells in 1-5% of leukemic cells. Swine cells continued to produce infectious adenovirus after 3 months in culture. End-medium harvested from leukemic swine cells produced a cytopathic effect in monolayer cultures of stable porcine embryonic kidney cell line; the agent causing this cytopathic effect was shown to be an adenovirus. The leukemogenic agent in ^{90}Sr -induced swine was thought to be the C-type virus particle, the adenovirus being a contaminant which may or may not enhance the leukemogenic process in these cells.

39 LEUKEMOGENIC EFFECT OF RADIOSTRONTIUM (^{90}Sr) IN MICE: A COMPARATIVE STUDY OF LEUKEMOGENICITY OF ^{90}Sr AND X-RAYS: I. INCIDENCE AND CHARACTERISTICS OF ^{90}Sr -INDUCED AND X-RAY-INDUCED LEUKEMIAS. (Jap.) Ito, T. (Res. Inst. Nucl. Med. Biol., Hiroshima U., Japan). *Acta Haemat Jap* (4):415-431, 1970.

Female mice subjected to 680 r of total-body X-irradiation developed leukemia in 77.3% of cases, after a latency period of 93-208 days; most leukemias were of thymic origin and lymphoblastic cell type. The incidence of leukemia induced by X-irradiation was reduced by thymectomy. Mice given 1 i.p. dose of $1\text{ }\mu\text{C/g}$ ^{90}Sr developed leukemias in 61.8% of cases after latencies ranging from 110-240 days; leukemias induced by ^{90}Sr originated in peripheral lymph nodes but not in the thymus, with the major radiation injury being confined to bone marrow cells. ^{90}Sr -induced leukemias were of lymphoblastic, reticulum cell or stem cell type. Thymectomy of mice did not affect the incidence of leukemias induced by ^{90}Sr . X-irradiation may have produced leukemic progenitor cells in the thymus, bone marrow and/or spleen; progenitor cells may then have migrated to the radiation-injured thymus and proliferated there. ^{90}Sr may have produced similar progenitor cells in the bone marrow by the internal emission of β -rays, with the progenitor cells migrating to peripheral lymphoid tissues. While ^{90}Sr -induced leukemic cells might remain as primitive undifferentiated cells in the peripheral lymphoid cells, X-ray-induced leukemia cells may be able to undergo lymphoid differentiation in the thymus as a result of the action of a hypothetical thymic factor.

1840 LEUKEMOGENIC EFFECT OF RADIOSTRONTIUM (^{90}Sr) IN MICE: A COMPARATIVE STUDY OF LEUKEMOGENICITY OF ^{90}Sr AND X-RAYS: II. TRANSMISSIBILITY OF THE INDUCED LEUKEMIAS, ALKALINE PHOSPHATASE ACTIVITY AND CYTOGENETIC CHANGES OF LEUKEMIC CELLS. (Jap.) Ito, T. (Res. Inst. Nucl. Med. Biol., U. Hiroshima, Japan). *Acta Haemat Jap* 33(4):432-448, 1970.

Newborn mice of various strains were given inoculations of cell-free extract prepared from leukemias induced in mice by i.p. administration of ^{90}Sr or fractionated total-body X-irradiation. Five of 8 cases of leukemia induced by ^{90}Sr were transmitted to recipients with latencies of 73-547 days. The leukemogenic potency of ^{90}Sr -induced cell-free extract was in the 9-33% range. Three of 4 cases of X-irradiation-induced leukemia were transmitted to recipients with latencies of 240-464 days, and the leukemogenic potency of these extracts was comparable to that of extracts of ^{90}Sr -induced leukemias. These results suggested that a virus may play a role in the induction of leukemia by ^{90}Sr and by X-irradiation. In X-ray-induced leukemias, alkaline phosphatase activity was negative or moderate, while in ^{90}Sr -induced leukemias, alkaline phosphatase was markedly elevated. Leukemias induced by ^{90}Sr and transmitted to mice generally showed negative or moderate alkaline phosphatase activity. Aneuploidy, polyploidy and pseudo-polyploidy were common in cells of leukemias induced by ^{90}Sr or X-irradiation. Metacentric, minute and giant chromosomes were seen in 2 leukemias, 1 induced by ^{90}Sr or X-irradiation. Cell-free passaged leukemias originally induced by ^{90}Sr had relatively few chromosome aberrations.

1841 EXPERIMENTAL INDUCTION OF PORCINE LEUKEMIA. (E.) Howard, E. B. (Battelle Mem. Inst., Pacific Northwest Lab., Richland, Wash.). *Bibl Haemat* 36:430-439, 1970.

Pitman-Moore miniature swine which were fed ^{90}Sr in amounts ranging from 1-3100 $\mu\text{C/day}$ developed 69 cases of hematopoietic disease arising, 49 of which were disturbances of myelogenic tissue. There were 29 cases of myeloid metaplasia, 3 cases of stem cell neoplasms, 22 cases of myeloid neoplasms, and 17 cases of lymphoid neoplasms. Myeloid metaplasia was generally associated with higher daily dose levels of ^{90}Sr , as were myeloid neoplasms. In the latter category, pigs showed leukopenia progressing into myeloblastic leukemia at varying times before death. Blast cells in these animals were usually negative for peroxidase and alkaline phosphatase. Granulocytic leukemia, eosinophilic and basophilic leukemia were also observed in the myeloid neoplasm experimental group. Lymphoid conditions, usually lymphoma, generally occurred in the progeny of ^{90}Sr -fed swine. To test the immunocompetence of ^{90}Sr -fed swine, animals were inoculated with *Brucella abortus* antigen and their antibody response was tested by the plate agglutination test. Strontium-fed pigs showed a

reduced capacity to produce antibody to *Brucella* compared to controls, maximum antibody titers in the experimental and control groups measuring 2.5×10^2 and 5.3×10^2 at 1 wk postinoculation.

1842 RADIATION STUDIES ON MICE OF A NATURALLY TUMOR-RESISTANT STRAIN (X/Gf): NUCLEOLAR MORPHOLOGY OF THYMIC LYMPHOCYTES DIFFERING IN RADIO-SENSITIVITY. (E.) Potmesil, M. (Dept. Biol., New York U., New York, N.Y.) and A. Goldfeder. *Radiat Res* 46(2):394-408, 1971.

A tumor-resistant strain of mice (strain X/Gf) was subjected to whole-body X-irradiation in doses of 100-1000 r (single exposure) and were killed 24 hr after irradiation; another experimental group was given a single dose of 300 r and animals were killed 3, 24, 48 or 96 hr or 7 days after irradiation. Thymic lymphocytic cells from irradiated mice were found to have ring-shaped nucleoli, trabeculated nucleoli, dense nucleoli, or nucleoli having combinations of these features. Twenty-four hr after 300 r treatment, the absolute number of mature lymphocytes in mouse thymuses had decreased 80%, the number of promyelocytes by 72%, and the number of lymphoblasts by 58%. Lymphocytes with ring-shaped nucleoli declined more markedly following irradiation than lymphocytes with trabeculated nucleoli, and lymphocytes with both types of nucleoli declined far more markedly than either type. During lymphocyte regeneration, the increase in lymphocytes with trabeculated nucleoli preceded the increase in lymphocytes with the other 2 types of nucleoli. Mature lymphocytes and promyelocytes with ring-shaped nucleoli were found to be the most radiosensitive cell population examined, having a 37% effective dose (D_{37}) of 140 r. Mature lymphocytes and promyelocytes with trabeculated nucleoli had a D_{37} of 335 and 460 r, resp. Lymphoblasts having both ring-shaped and trabeculated nucleoli had a D_{37} of 275 r. Also radioresistant were lymphoblasts with trabeculated nucleoli ($D_{37}=400$ r) and lymphoblasts with dense nucleoli ($D_{37}=500$ r).

1843 FINE STRUCTURE OF ALVEOLAR AREAS IN THE LUNG FOLLOWING INHALATION OF $^{239}\text{PuO}_2$ PARTICLES. (E.) Sanders, C. L. (Batelle-Northwest Lab., Richland, Wash.). R. R. Adey and T. A. Jackson. *Arch Environ Hlth* 22(5):525-533, 1971.

Female rats were exposed to an aerosol of $^{239}\text{PuO}_2$ with an exposure time of 4 min; estimated mean radiation dose in rads absorbed by the lung ranged from 300-13,900 rads. In lung tissue specimens prepared 7 days after exposure to the aerosol, many $^{239}\text{PuO}_2$ particles were seen in macrophages in the lung; the number of macrophages increased in specimens taken from rats exposed at 12, 18-20 and 30 days before preparation of specimens and decreased in specimens prepared 40 and 50 days after exposure. Structural alterations associated with $^{239}\text{PuO}_2$ exposure grew increasingly severe with time after exposure. Plasma cells, histiocytes, septal cells, alveolar exudate, lipid droplets, collagen and elastin all increased from 21 to about 40 days after exposure to

$^{239}\text{PuO}_2$; by 55 days, most changes had either leveled off or decreased. The alveolar exudate was composed of myeloid bodies, cell debris and a protein-like material. During the terminal phase of radiation pneumonitis alveolar type A cells were seen to be damaged.

1844 THE DYNAMICS OF MITOTIC ABERRATIONS INDUCED IN THE WHITE RAT BY A SINGLE DOSE OF 800r. (E.) Anastasiu, Gh. (Med. Fac. Bucarest, Rumania) and O. Cilievici. *Arch Roum Path Exp Microbiol* 29(1-2):81-89, 1970.

In the first 2 days following a single dose of 800 r of X-irradiation, the mitotic index in the femoral bone marrow of rats was at or above control levels (control mitotic index = 10.3%); between 4-15 days postirradiation, mitotic indices dropped to 5.6-8.6% rising again by day 60 to 8.7%. In the first 7 days following irradiation, aberrant mitoses prevailed in rat bone marrow, with more than 50% of mitoses being abnormal. From day 15 forward, however, the percentage of aberrant mitoses declined, and 8% of mitoses were abnormal by day 60 postirradiation. In the first 7 days postirradiation, aberrations including chromosomal fragmentation at the centromere, acentric fragmentation, agglutination, deletion, translocation, gaps and breaks were frequent; from day 15 to day 60, aberrations of the various types began to decrease, and by day 60 only breaks and polyploidies were found. Total aberrations decreased from a high of 201 on day 2 to 18 on day 60.

1845 SPECIFIC PRETUMORAL AND TUMORAL PROCESSES OCCURRING IN MOUSE OVARIES FOLLOWING EXPOSURE TO HIGH DOSES OF IONIZING RADIATION. (Rus.) Aleksandrov, S. N. (Central Res. Inst. Radiol., Leningrad, U.S.S.R.), A. V. Gubareva and K. F. Galkovskaya. *Vop Onkol* 17(1):51-54, 1971.

The dynamics of radiation-induced ovarian tumorigenesis in mice subjected to non-irradiated bone marrow autotransplantation were investigated. Four groups of virgin rambred mice (a total of 600) were exposed to single doses of γ -irradiation of 600, 900, 1100, or 1200 rads, resp., and treated with autologous bone marrow extracted prior to exposure. Three control groups were used: a) intact mice exposed to similar irradiation doses with no further treatment b) non-irradiated mice subjected to bone marrow autotransplant; c) intact mice with no treatment. The animals exposed to 1100 and 1200 rads were given streptomycin (500 U twice daily at 6 hr intervals for 10 days) in addition to bone marrow starting on the 3rd day after the exposure. Bone marrow autotransplant had no effect on the incidence of ovarian tumors in mice exposed to 600 or 900 rads. Whole body irradiation with 1200 rads led to 100% mortality. No hyperplastic alterations of the ovaries were seen during the first months following exposure to 1100 rads in the 203 animals that survived the acute radiation illness stage with the protective autotransplant treatment. Severe vascular damage and long lasting atrophy of the thecal tissue

appeared to be important factors in the development of ovarian tumors. The first tumor, which occurred during the 11th month following exposure to 100 rads, had the structure of a tubular adenoma with an inert stroma; such adenomas are usually rare in animals exposed to lower doses of ionizing radiation. Their average life span was 470 days and similar to that of the animals exposed to 900 rads (477 days), but the tumor incidence of 18% was lower than the latter group and similar to the control groups. Carcinogenesis under conditions of exposure to high doses of ionizing radiation seems to be induced by penetrating radiation effects and to be unrelated to spontaneous blastomogenesis. Decrease of tumor incidence in mice exposed to high doses of irradiation seems to be due to the suppression of gonadotropic activity of the pituitary gland, reflected in the atrophy of the ovarian theca, and to severe vascular damage.

- 46 THE POSSIBLE CARCINOGENIC EFFECTS OF RADIATIONS ON THE UTERUS. (E.) Bird, C. (Imp. Cancer Res. Fund, London, England) and A. Willis. *Brit J Cancer* 24(4):759-768, 1970.

The carcinogenic effects of radium and X-rays on the rat uterus were studied with the object of determining successful induction of mixed endometrial tumors in response to radiation. In 20 rats treated with radium, 2 developed adenocarcinoma and a squamous cell carcinoma by comparison to 10 control rats with negative findings. Of 10 rats treated with 500 rad X-rays, 1 developed a leiomyoma; with 1000 rad, 1 adenocarcinoma and 1 adenosarcoma were found among 10 rats. Nineteen allografts treated with 500 rad and 1000 rad resp., failed to develop tumors; endometrial polyps occurred in a proportion of the rats in all groups receiving radium X-ray treatments. A variety of other extrauterine tumors occurred in both irradiated and control rats with mean tumor induction significantly reduced to 44.6 and 50.0 wk with 500 and 1000 rad dose, resp., compared to 73.6 wk in controls. Mammary tumors, principally adenocarcinomas and fibroadenomas, were found most frequently in the allografted X-irradiated rats. Experiments show that endometrial adenocarcinomas can be induced by intrauterine radium application or X-irradiation of the uterus from without.

- 47 INDUCTION OF MAMMARY NEOPLASIA AFTER IN VITRO EXPOSURE TO X-RAYS. (E.) Hellabarger, C. J. (Brookhaven Natl. Lab., Upton, N.Y.). *Proc Soc Exp Biol Med* 136(4):1103-1106, 1971.

Dominal-inguinal mammary tissue was excised from rats and exposed to a total of 800 r X-irradiation over a 2 min period; irradiated and sham-irradiated tissues were then replaced in the rats from which they had been taken. Of 110 irradiated grafts, 16 had developed mammary neoplasia 10 months after the graft; of the 16 neoplasms, 13 were fibroadenomas and 3 were adenocarcinomas. Of the 110 sham-irradiated

mammary tissue grafts, 1 developed neoplasia (a fibroadenoma). *In situ* neoplasia was found in 8 of the 110 rats given irradiated grafts; 6 of these neoplasms were fibroadenomas, 2 on the side opposite the side receiving the mammary tissue graft.

- 1848 THE ROLE OF MICROENVIRONMENTAL FACTORS IN HEMATOLOGIC RESPONSE OF MICE EXPOSED TO 1000 R "SPLIT DOSE" IRRADIATION AND TESTOSTERONE TREATMENT. (E.) Hajdukovic, S. (Biol. Div., Inst. "Boris Kidric", Belgrade, Yugoslavia). *Strahlentherapie* 141(4):464-471, 1971.

C57BL mice were exposed to 400 r of whole body irradiation followed by a dose of 600 r administered to the exteriorized spleen and hind leg. Following irradiation, the mice were treated with 2.5 mg of testosterone. During the first wk after irradiation, testosterone treated mice showed decreases in spleen weight. During the second postirradiation wk, spleen weight increased markedly in groups receiving testosterone treatment immediately after irradiation. Increases to a lesser degree were found in mice receiving testosterone treatment which had been delayed 24 hr or more after irradiation. The number of spleen cells was very depressed 8-10 days after irradiation in all testosterone treated mice. This contrasted with an increased spleen cell count found in the control group. During the second postirradiation wk the number of spleen cells increased in mice receiving testosterone immediately after irradiation. No similar increase was found in mice receiving delayed testosterone treatment. Testosterone treatment, whether initiated immediately after irradiation or later, stimulated erythroid regeneration in the bone marrow. Irradiated mice not treated with testosterone did not show stimulation of erythroid regeneration.

- 1849 RADIATION-INDUCED FIBROSARCOMA. (E.) N. F. C. Gane (Mount Vernon Hosp., Northwood, Middlesex, England), R. Lindup, P. Strickland and M. H. Bennett. *Brit J Cancer* 24(4):705-711, 1970.

In a series of 220 patients with fibrosarcoma, 6 cases were discovered in which the development of the lesion followed massive doses of therapeutic X-irradiation. Patients developed fibrosarcomas at the orbit, tongue, chest wall and femur after periods of 5-33 yr had elapsed since doses of X-irradiation ranging from 2600-8000 r had been administered.

- 1850 INTERFERENCE-MICROSCOPIC STUDY OF DRY WEIGHT AND WATER CONTENT IN BRONCHIAL EPITHELIAL CELLS IN RABBITS AFTER Co^{60} -GAMMA IRRADIATION. (Ger.) Nikulin, A. (Med. Fac. Sarajevo, Yugoslavia), B. Pikula, P. Plamenac and J. Djordjevic. *Beitr Path* 142(3):235-243, 1971.

Rabbits were exposed to Co^{60} γ -irradiation (4,760 r), and cells from their bronchial epithelium were removed and studied by interference microscopy. The volume and water content of bronchial epithelial cells'

nuclei and cytoplasm were increased by 60% and 23%, resp., in the first 12 hr postirradiation. Fluid contents of nuclei and cytoplasm declined after 3-4 days postirradiation, but did not approach normal levels until 10 days postirradiation. The dry weight of nuclei and cytoplasm increased following irradiation, but the dry weight increase was not as marked as the increase in water content. Osmotic changes brought about by irradiation were thought to have caused the changes in volume and water content of irradiated cells.

- 1851 *IN VITRO* IRRADIATION OF EMBRYONIC HAMSTER FIBROBLASTS WITH ULTRAVIOLET LIGHT OF 280 nm. (Ger.) Buder, E. (German Acad. Sci., Berlin, Germany), I. Rahn, T. Schramm and R. Wetzell. *Arch Geschwulstforsch* 36(4):335-338, 1970.

Fibroblast cultures from embryonic golden hamster tissues cultivated for 21-40 days were irradiated 5-10 times with UV light at 280 nm at a previously empirically determined optimal dosage of 1.0×10^4 erg/cm². The 40-day cultures were harvested manually and 1×10^6 to 5×10^6 cells, suspended in nutrient medium, were injected s.c. in each of a series of 48 hr old Syrian hamsters. Systematic examination over 5-7 months failed to disclose any evidence of tumor formation in the 21 animals treated. Similarly, *in vitro* preparations showed no indications of malignant cell forms. The findings in these experiments using 280 nm light are considered negative.

- 1852 EPITHELIAL OUTGROWTHS FROM LUNG TISSUE FOLLOWING INTRAPLEURAL INJECTION OF ASBESTOS DUST IN EXPERIMENTAL ANIMALS. (E.) Davis, J. M. G. (Dept. Path., Cambridge U., England). *Int J Cancer* 7(2):238-248, 1971

Chrysolite and crocidolite asbestos dust particles (25 mg suspended in water) were injected into the pleural cavity of rats, mice and hamsters, and the animals were examined for pleural lesions at intervals from 7 days to 4 yr later. Treated animals developed granulomas and areas of the pleural surface became thickened with fibrous tissue. Granuloma cells either phagocitized or surrounded the injected dust. Clefts lined with epithelial cells formed outside the original line of the pleural surface and grew into the granulomas and areas of fibrous pleural thickening. The cells in these clefts, while originally showing the structure of surfactin-secreting alveolar cells, later lost their surfactin granules and became ciliated. Cysts formed from clefts in some animals, and groups of cysts grew from the lung tissue to invade the areas of pleural fibrosis. Like the clefts, the cysts were lined with surfactin-secreting alveolar cells.

- 1853 CARCINOGENIC PROPERTIES OF WEAR PARTICLES FROM PROSTHESES MADE IN COBALT-CHROMIUM ALLOY. (E.) Heath, J. C. (Strangeways Res. Lab., Cambridge, England), M. A. R. Freeman and S. A. V. Swanson. *Lancet* 1(7699):564-566, 1971.

Prosthetic devices for the replacement of hip and knee joints were worked mechanically in a medium containing either Ringer's solution or synovial fluid at 37°C, and a deposit of wear particles was collected. The prostheses were made of a cobalt-chromium alloy, and the wear particle deposits consisted of 66% cobalt and 26% chromium. Samples of the wear debris were injected into skeletal muscles of female rats. Fourteen rats developed sarcomas 4-15 months after injection of the debris. Tumors included osteofibrosarcomas, cellular sarcomas and anaplastic rhabdomyofibrosarcomas. Tumors metastasized to lymph nodes in the thigh and to the prevertebral lumbar region.

- 1854 MEDICAL X-RAY EXPOSURE AMONG HIROSHIMA AND NAGASAKI A-BOMB SURVIVORS. (E.)

Russell, W. J. (Atomic Bomb Casualty Comm., Hiroshima Japan). *Nippon Acta Radiol* 30(10):12-54, 1971.

Of 20,000 persons examined in Hiroshima and Nagasaki since 1957, 23% of the Hiroshima and 12% of the Nagasaki group had received therapeutic or diagnostic X-irradiation. More survivors of the nuclear bomb attacks on Hiroshima and Nagasaki reported exposure to medical X-rays than did persons not exposed to radiation at the time of the attacks in 1945. In Hiroshima, the sites most frequently exposed to therapeutic X-irradiation were the lymph nodes of the neck, the thyroid and the uterus. Cumulative medical X-ray doses approached doses incurred by atomic bomb survivors who were 2200 m from the explosion hypocenter in Hiroshima and 3200 meters from the hypocenter in Nagasaki. Skin doses of X-irradiation averaged 43.5 rads in Hiroshima and 12.8 rads in Nagasaki. Gonadal doses in Hiroshima and Nagasaki for males were 118 and 37.4 mrad, resp, and for females, 1652 and 413 mrad, resp. The integral bone marrow dose in Hiroshima and Nagasaki was 1269 and 454 g-rads, resp.

- 1855 ULTRASTRUCTURE OF HUMAN EPIDERMIS FOLLOWING CHRONIC SUN EXPOSURE. (E.) Everett, M. A. (U. Oklahoma Med. Ctr., Oklahoma City), J. Nordquist and R. L. Olson. *Brit J Derm* 84(3):248-257, 1970.

Biopsy specimens from 6 elderly, fair-skinned male farmers were prepared from areas of the body exposed to sunlight and from unexposed areas; the patients had histories of actinic keratoses and skin cancer. Under the light microscope, the exposed skin showed effaced rete ridges and decrease in epidermal thickness. Ultrastructurally, unexposed skin showed no prominent abnormalities; exposed skin showed great variability in quantity and morphology of desmosomes, ribosomes, endoplasmic reticulum, mitochondria and melanosomes. Keratinocyte morphology varied from normal to severely disordered. Abnormal tonofilament morphology within basal cells was the most consistent and characteristic abnormality; most tonofilaments were abnormally short, and filaments were often fused. Degenerative changes resembling dyskeratosis were seen in spinous and basal cells, and cellular cohesion was

disturbed. Melanin distribution in exposed skin was abnormal, varying from areas of excessive melanin content to areas in which pigment was absent. Melanosome complexes were often larger than normal. These changes in exposed skin were often seen under the electron microscope when no light microscopic or clinical abnormalities were observable.

1856 EFFECTS OF LIGHT ON SKIN LIPID METABOLISM.
(E.) Black, H. S. (VA Hosp., Houston, Tex.) and E. W. Rauschkolb. *J Invest Derm* 56(5): 387-391, 1971.

Fresh human skin obtained from the lower abdomen of male Caucasian subjects was exposed to broad-spectrum light in doses which exceeded by a factor of 10 the amount of light needed to produce erythema. Six hr after exposure, total lipid, free sterol, neutral fat and phospholipid were assayed in the irradiated skin. Values for total lipid incorporation of C^{14} -acetate were 51% of control values in irradiated skin, and phospholipids in irradiated skin were at 15% of control values. Sterols in irradiated skin incorporated 48% of the C^{14} -acetate incorporated by control sterols, and neutral fat incorporation was 47% of the value of control fat incorporation in irradiated skin. Levels of C^{14} -acetate incorporation into digitonide-precipitable sterols in irradiated skin were 58% of their values in controls, while levels of C^{14} -mevalonate incorporation into these sterols in irradiated skin were 96% of control values. Studies on porcine skin suggested that the reduction in acetate incorporation into lipids resulted from altered synthesis of lipids. The light susceptible site of sterol synthesis was thought to lie along the biosynthetic pathway between acetate and mevalonate.

1857 STUDY OF ASBESTOS WORKERS IN BRITISH COLUMBIA. (E.) Hurlburt, J. F. (Dept. Med. III, U. British Columbia, Vancouver, Canada) and N. G. Schulson. *Brit Columbia Med J* 13(3):58, 67-68, 1971.

Thirty-three asbestos workers from the Vancouver area, 20 with histories of exposure in excess of 20 yr, were tested to determine whether exposure to asbestos dust had impaired pulmonary function. Twelve of the 33 men tested had chronic coughs; 22% of the former cigarette smokers and 70% of all present cigarette smokers had chronic coughs. Three men who had been exposed to asbestos dust for more than 10 yr had experienced recurring asthmatic attacks. Six of the 33 men tested had vital capacities that were below 80% of the predicted normal values in pulmonary function tests; all these men had been exposed to asbestos dust for more than 15 yr. Thirteen of the subjects showed abnormally low (i.e., below 75% of normal) forced expiratory volume in 1 second. Abnormal scores in forced expiratory volume tests among asbestos workers were found to be correlated with cigarette smoking; 70% of all those with abnormal scores were present smokers. Cytological screening showed 1 subject with Class II and another with possible Class II cells. One sub-

ject showed scattered opacities in the upper portions of the right lung which may have represented pleural plaques.

1858 DIFFUSE MALIGNANT PLEURAL MESOTHELIOMA AND ASBESTOS EXPOSURE. (E.) Whitwell, F. (Broadgreen Hosp., Liverpool, England) and R. M. Rawcliffe. *Thorax* 26(1):6-22, 1971.

Of 52 cases of pleural mesothelioma collected in the Liverpool area from 1955-1970, 20 were cases of tubulo-papillary tumor and 11 were sarcomatous, with 18 cases of "mixed" histological type. The tumors were invasive and metastasizing; distant metastases were found in 14 of 22 necropsies among the 52 cases. Common sites for blood-borne metastases were the liver and lung. Seventy-five percent of the patients were between 50-70-yr-old, and 77% of them were male. Fifty-three percent of the patients survived 1 yr from the onset of pleural mesothelioma symptoms, 17% survived 3 yr and 8% survived over 5 yr. Thirty-five of 40 male cases and 8 of 12 female patients had experienced significant exposure to asbestos dust in the course of their working lives, often as employees in the shipbuilding industry in Liverpool. Duration of exposure to asbestos dust ranged from 3 to more than 50 yr, and the interval between first asbestos exposure and onset of mesothelioma symptoms usually exceeded 25 yr (mean = 42 yr). Seventeen percent of the patients showed basal asbestosis in their lungs, and asbestos bodies were found to excess in the lungs of nearly all the patients.

1859 HISTOLOGIC TYPES OF LUNG CANCER AMONG URANIUM MINERS. (E.) Saccomanno, G. (VA Hosp., Grand Junction, Colo.), V. E. Archer, O. Auerbach, M. Kuschner, R. P. Saunders and M. G. Klein. *Cancer* 27(3):515-523, 1971.

In a survey of 121 cases of lung cancer among American uranium miners, the frequency of incidence of oat cell carcinoma and small cell undifferentiated (polygonal cell) carcinomas was found to increase with radiation exposure up to 1500 working level months (WLM). At 1500 WLM, 50% of the cancers observed were small cell undifferentiated polygonal cell type and 25% were small cell undifferentiated oat cell type. Epidermoid carcinomas and other types of carcinoma decreased in incidence to 2000 WLM of exposure, with frequencies leveling off at higher exposures; 17% of cancers were epidermoid cancer and 5% were other carcinoma cell types at 3000 WLM. An average of 15.9 yr was round to elapse between beginning of mining and onset of cancer. Workers exposed to uranium radiation for 2501-9700 WLM showed the longest induction-latent period (18.2 yr) and workers exposed to radiation for 201-700 WLM showed the shortest induction-latent period (10.6 yr). In miners of all ages and with all observed histories of cigarette smoking, exposure to radiation increased the incidence of small cell undifferentiated carcinoma and decreased the incidence of epidermoid carcinoma. Although the frequency of epidermoid cancer was greater among older miners than among younger miners, there was no observable correlation between epidermoid carcinoma

and cigarette smoking. Younger heavier smokers had higher frequencies of oat cell carcinoma than light smokers of the same age.

- 1860 GENERALIZED PARAFFINOMA (SCLEROSING LIPO-GRANULOMA). (E.) Urbach, F. (Temple U. Hlth. Sci. Ctr., Philadelphia, Pa.), S. S. Wine, W. C. Johnson and R. E. Davies. *Arch Derm* 103(3): 277-285, 1971.

Sclerosing lipogranuloma was developed by a 30-yr-old woman who had received multiple injections of mineral oil totaling 1 liter in the calves of her legs. Less than 2 yr after the treatment, large plaques of indurated thickened skin appeared on her legs. Roentgenograms of the chest showed fine nodular densities scattered throughout both lungs; these were thought to be secondary to microembolization of lipid from the mineral oil injections in the legs. Pulmonary function tests showed an inspiratory capacity 50% of the predicted norm. Sclerosing lipogranuloma was found in skin from the right calf and thigh. Sections from the lung showed many noncaseating granulomatous lesions with large multinucleated giant cells. Sections of lymph node showed many tissue spaces. Mineral oil was determined to be the agent responsible for the changes observed in the patient's tissues.

VIRAL CARCINOGENESIS

365 LEUKEMIA OF GUINEA PIGS. (E.) Ioachim, L. (Lenox Hill Hosp., New York, N. Y.) and L. Warwick. *Bibl Haemat* 36:566-573, 1970.

Transmission of a spontaneous leukemia arising in guinea pigs by inoculation of animals with suspensions of leukemic cells or with plasma produced leukemias in recipient guinea pigs within 12-15 days after injection of cell suspensions and after 18-20 days following injection of plasma. In inoculated guinea pigs, white blood cell counts rise from 2-100,000 elements/ml. Leukemic guinea pigs died within a few days after onset of symptoms, and the major organs involved were spleen, liver and lymph nodes. Virus particles having diameters of 800-1000 Å were found in leukemic guinea pigs in the area of the nuclear envelope and in the cisternae of the endoplasmic reticulum of cells. These particles had the shape of C-type particles, but their nucleoids were not as electron-dense as those of C-type particles. Leukemia could not be induced by inoculating guinea pigs with cell-free filtrates of leukemic cells.

366 COMPARISON OF LEUKEMOGENIC AND SARCOMAGENIC VIRUSES AT THE ULTRASTRUCTURAL LEVEL. (E.) Ochowski, L. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston). *Bibl Haemat* 36:62-82, 1970.

Following a review of the literature of the morphology and species-specificity of RNA viruses, a comparison of leukemogenic and sarcomagenic RNA virus particles in animals of different species at the ultrastructural level was described. Mouse mammary tumors harbored virus particles not easily classified as either B or C type; particles took several different forms including budding forms, multinucleate forms and amorphous forms. Particles found in murine leukemias, solid tumors and in some mammary tumors included mature and immature forms. B and C type virus particles were found in some mouse mammary tumors, as were particles of an undefined type resembling "H" type particles. Murine leukemias and reticulum cell sarcomas contained characteristic cylindrical particles. Type "H" particles were found in rat and hamster bone tumors as well as in mammary tumors. Type C particles differing in the density of the nucleoid of particles in different tumors were found in bone tumors of mice, in feline lymphomas, and in human leukemias. Esh sarcomas also contained type particles like those found in chickens with Marek's disease.

367 STUDIES ON THE CONJECTURAL VIRUS NATURE OF HUMAN LEUKEMIA IN EXPERIMENTS ON MONKEYS. (E.) Yakovleva, L. A. (USSR Acad. Med. Sci., Sukhumi). *Bibl Haemat* 36:761-772, 1970.

Macaque monkeys (*Macaca mulatta* and *M. speciosa*) and hamadryas baboons (*Papio hamadryas*) were inoculated with whole heparinized or citrated blood from human patients with stem cell leukemia or chronic myeloid leukemia. Inoculated monkeys included newborns of both sexes, fetal monkeys, pregnant females and adults of both sexes aged from 1-3 yr. Inoculations

produced enlarged lymph nodes and splenomegaly in macaques, often leading to death; autopsy revealed focal proliferation of young reticular and undifferentiated blast cells in bone marrow and spleen. *M. speciosa* were more susceptible to the effects of the inocula than were *M. mulatta*. Baboons did not develop the symptoms observed in macaques; however, some inoculated female baboons developed symptoms of leukosis-reticulosis by 1.5 yr postinoculation. Among both macaques and baboons, pregnant females inoculated with leukemic cells *in utero* during pregnancy were especially susceptible. Uninoculated monkeys maintained in the vicinity of the inoculated animals developed mild leukemias. Leukocytes of all affected monkeys were found to possess a surface antigen. The passage of blood from inoculated and symptomatic monkeys to other monkeys produced symptoms similar to those manifested by the donors, and recipient animals demonstrated the surface antigen found in affected inoculated monkeys.

1868 SIGNIFICANCE OF VIRUS PARTICLES OBSERVED IN SPONTANEOUS AND INDUCED TUMORS OF THE SYRIAN HAMSTER. (E.) Stenback, W. A. (Baylor Coll. Med., Houston, Tex.), G. L. Van Hoosier, Jr., D. B. Ferguson and J. J. Trentin. *Bibl Haemat* 36:559-565, 1970.

An isolated and supposedly virus-free hamster colony was surveyed for tumor incidence and for the presence of viruses. Of 106 hamsters tested for viral antibodies by means of the hemagglutination inhibition test, 2 were found to harbor antibodies to reovirus type 3. Of 1671 animals in the colony, 8 developed spontaneous malignant neoplasms which were detected at necropsy at 188 days of age or older. Six of these tumors arose in hamsters 12 months of age or older, and 3 of them were lymphomas involving lymph nodes. Other tumors were kidney carcinoma, adenocarcinoma metastasizing to the mesenteric lymph nodes, myxoid liposarcoma of the cheek pouch, hemangio-pericytoma of the cheek pouch and undifferentiated sarcoma involving the subcutis. C-type particles were found in lymphomas, and "Bernhard" virus particles were also found to be endemic in hamsters in the colony. One malignant lymphoma arose in 1 of 29 hamsters exposed to 4 equal doses of 240 r irradiation at 7 day intervals; this tumor was transplantable and contained clusters of A-type viral particles, as well as C-type and "Bernhard" virus particles.

1869 INTRACISTERNAL TYPE A PARTICLES AND PROPERTIES OF A CONTINUOUS CELL LINE ORIGINATING FROM A GERBIL FIBROMA. (E.) Tumilowicz, J. J. (Inst. Med. Res., Camden, N. J.) and J. J. Cholon. *Proc Soc Exp Biol Med* 136(4):1107-1110, 1971.

An explanted fibroma from the dorsal surface of the paw of a gerbil was prepared for culture and passaged more than 70 times. The tumor consisted of fibroblast-like cells and had a doubling time in culture of 36-38 hr. In the fifth passage, the modal chromosomal number of the tumor cells was 44 with 22% of the cells deviating from this norm; by passage 52,

all cells examined were heteroploid. Ultrastructurally, the salient features of the gerbil fibroma cell line were well developed rough endoplasmic reticulum often showing distended cisternae, intricately ruffled or lobed nuclear membranes, and a particle resembling the intracisternal A-type particle. Type A particles were rare and were usually solitary; budding particles were extremely rare. Although particles were found in cells in culture, none could be found in cells from the tumor itself. No mycoplasma could be isolated from the tumor cells. The cells were susceptible to adenovirus 12, herpes simplex virus and reovirus 3, and resistant to poliovirus 1 and echovirus 11. Hamsters inoculated with gerbil fibroma cells developed regressing nodules but no progressive tumors.

- 1870 'C'-TYPE VIRUS PARTICLES IN RAT TUMORS. (E.) Chopra, H. C. (John L. Smith Mem. Cancer Res., Chas. Pfizer & Co., Maywood, N. J.) and R. M. Dutcher. *Bibl Haemat* 36:584-592, 1970.

Mammary carcinomas induced in rats by various means and transplanted rat leukemias were examined microscopically for the presence of C-type virus particles. Rat mammary tumors were primary and/or transplantable dimethylbenzanthracene-induced carcinomas, tumors induced by methylcholanthrene, diethylstilbestrol-cholesterol-induced tumors, spontaneous tumors, X-ray-induced tumors and mammary adenocarcinoma R-35. Virus-like particles resembling C-type particles were found in neoplastic cells of transplanted mammary tumors but not in primary tumors; C-type particles were most abundant in mammary adenocarcinoma R-35. Older necrotic tumors and new transplants yielded the least amounts of particles. C-type particles were scarce in transplanted methylcholanthrene- and diethylstilbestrol-cholesterol-induced tumors. Rat leukemias also contained C-type particles; however, the size and morphology of these particles was more variable than those seen in mammary tumors.

- 1871 L₂C/NB GUINEA PIG LEUKEMIA: FAILURE TO DEMONSTRATE TRANSMISSIBLE LEUKEMOGENIC VIRUS. (E.) Sarma, P. S. (Natl. Inst. Hlth., Bethesda, Md.), P. J. Ueberhorst, V. Zeve, J. Whang-Peng and R. Huebner. *Bibl Haemat* 36:574-577, 1970.

Although it was not possible to transmit leukemias from L₂C strain 2 guinea pigs by means of cell-free filtrate inocula, the leukemia could be transplanted by inoculation of viable leukemic blast cells i.p., s.c., or intradermally to recipient guinea pigs. As few as 12 leukemic blast cells in the inocula successfully transmitted the disease. *In vitro* attempts to isolate and demonstrate a C-type RNA virus in leukemic guinea pig cells gave negative results; no antigens similar to avian or murine leukemia group-specific complement fixing antigens could be detected in guinea pig leukemic cells by complement fixation tests. Virus particles were not seen in guinea pig embryo fibroblast cultures inoculated with cell-free preparations of strain 2 guinea pig leukemic tissue. Chromosomal studies appeared to indicate that the fatal leukemia seen in strain 2 guinea pigs was caused by the proliferation of blast cells transplanted from the original leukemia which was from a strain 2 female guinea pig.

- 1872 BIOLOGICAL STUDIES WITH VIRAL INDUCED FIBROSARCOMAS IN CATS, DOGS, RABBITS AND NON-HUMAN PRIMATES. (E.) Theilen, G. H. (U. California Sch. Vetr. Med., Davis), S. P. Snyder, L. G. Wolfe and J. C. Landon. *Bibl Haemat* 36:393-400, 1970.

Fibrosarcomas induced in cats by virus and spontaneous fibrosarcomas served as the source for inocula which were given to kittens, puppies, rabbits, marmosets and monkeys of the genus *Macaca*. Fibrosarcomas were induced in all recipient groups with varying incidences. Of 65 kittens inoculated with filtrates or extracts from feline fibrosarcoma, 39 developed s.c. fibrosarcomas with a latency of 10-45 days; tumors were multiple and most were progressive. Fibrosarcoma filtrate developed tumors with latencies of 8-28 days; tumors were similar to those developed by kittens. All 3 rabbits given fibrosarcoma filtrates developed multiple tumors at the site of inoculation; the latent period was 12-20 days. No viral particles were found in the fibrosarcoma cells. Two marmosets given i.p. and s.c. inoculations of fibrosarcoma extracts developed invasive inguinal and intra-abdominal tumors after a latent period of 24-28 days; no C-type virions were seen in the neoplastic cells. *Macaca* monkeys developed tumors in 5 of 6 cases 15-17 days after inoculation. No viral particles were observed.

- 1873 FURTHER CHARACTERIZATION OF BOVINE LEUKEMIC CELL CULTURES. (E.) Lin, P. S. (Sch. Vetr. Med., U. Pennsylvania, Kennett Square), G. B. Guest, N. D. Stock and R. M. Dutcher. *Bibl Haemat* 36:465-470, 1970.

Indirect immunofluorescence tests carried out with bovine sera against infectious bovine rhinotracheitis virus and anti-parainfluenza III virus failed to show reactions with suspensions of cell lines established *in vitro* from mononuclear leukocytes of cattle with lymphosarcoma. However, all the bovine lymphosarcoma cell lines tested did react directly with bovine syncytial virus (BSV) fluorescein conjugated serum. The possibility that the lymphosarcoma cell lines contained BSV was further supported by the finding that syncytia appeared in subcultures of bovine lymphosarcoma cells co-cultivated with bovine embryonic monolayer cultures. Assays of supernatant fluids from lymphosarcoma cell lines were negative for interferon, and electron microscopic examination of lymphosarcomatous cell lines revealed no virus-like particles. Calves injected with cells from mixed cultures did not develop lymphosarcoma or leukemia; however, the lymphocyte counts of inoculated calves were above expectation.

- 1874 COMPARISONS OF VIRUS-LIKE PARTICLES FROM LEUKOTIC CATTLE TO FELINE LEUKOSIS VIRUS. (E.) Kawakami, T. G. (Sch. Vetr. Med., U. California Davis), A. L. Moore, G. H. Theilen and R. J. Munn. *Bibl Haemat* 36:471-475, 1970.

Virus-like particles purified from plasma of leukotic cattle had a buoyant density comparable to that of

feline leukemia virus; the bovine virus rested in sucrose gradients between 1.14 and 1.18 g/cm³. The sedimentation rate of the bovine virus-like particles was less than that of the feline leukemia virus, and the bovine particles were more variable morphologically than feline leukemia virus. Bovine virus-like particles were about 85-100 nm in diameter, whereas the diameter of the feline leukemia virus is approximately 115 nm. Bovine virus-like particles, like feline leukemia virus, appeared to replicate from lymphocytes by budding. No antigenic interactions between bovine virus-like particles and feline leukemia virus could be demonstrated by immunodiffusion tests.

- 1875 FURTHER STUDIES OF BOVINE SYNCYTIAL VIRUS. (E.) Van Der Maaten, M. J. (Agric. Res. Service, Ames, Iowa), A. D. Boothe and W. A. Almquist. *Bibl Haemat* 36:446-452, 1970.

Immunodiffusion tests were run on sera from 9 species to determine the presence in these species of bovine syncytial virus antigen; species tested were: mouse, hamster, guinea pig, rabbit, sheep, swine, bison, horse and man. None of the sera reacted positively. Five 10 of 10 rabbits and 2 of 4 sheep inoculated with bovine syncytial virus became infected with virus, no infection was produced by inoculation of mice, hamsters, guinea pigs or swine. Rabbits were infected successfully whether given concentrated or dilute virus inocula. Virus particles were found at surface membranes of cells of infected bovine embryonic spleen cells. Additional instances of bovine syncytial virus infection were found among normal and lymphosarcomatous cattle by immunodiffusion tests, with 21% of animals in normal herds showing infection, and 22% of lymphosarcomatous cattle showing infection.

- 1876 DETECTION OF A BOVINE VIRUS ASSOCIATED WITH SYNCYTIAL FORMATION IN MIXED CELL CULTURES. (E.) Cornefert-Jensen, F. (Sch. Vetr. Med., U. Pennsylvania, Philadelphia), N. D. Stock and R. R. Marshak. *Bibl Haemat* 36:453-464, 1970.

Human thoracic duct and peripheral blood lymphocytes from cattle with lymphosarcoma were co-cultivated with cultures of human diploid cells, embryonic bovine tracheal cells or bovine embryonic kidney cells, the lymphocytes from lymphosarcomatous cattle exhibited peripolesis and emperipolesis, attaching to and penetrating both human and bovine feeder cells. Peripolesis and emperipolesis became manifest on day 16 after the initiation of mixed cell cultures. Masked virus of uncertain type designated BSV was found in lymphosarcomatous bovine cells which produced a cytopathic effect in the feeder cells in mixed cell cultures; the cytopathic effect consisted of the formation of large syncytia, nuclear lobulation, microfragmentation, and cytoplasmic vacuolation. Co-cultivation of syncytia with normal bovine lymphocytes resulted in transfer of the cytopathic effect to the normal cells; however, none of the infected cell cultures yielded infectious virus. The original phenomena of cell attachment and penetration by

lymphosarcomatous cells may have played a role in the transfer of the viral genome from leukocytes to the feeder cells, the genome becoming reactivated upon entry into the feeder cells. Numerous virus-like particles could be seen in bovine cells cultures infected by co-cultivation with lymphosarcomatous lymphoid cells. Newborn calves of virus-infected animals did not carry BSV or BSV antibody; however, calves could be infected with BSV by injecting them with infected living cells from mixed cell cultures or with peripheral blood from infected cattle. None of the infected calves developed apparent lymphosarcoma. BSV infection was found to occur naturally in normal herds in approximately 4% of the cattle. The incidence of BSV infection was higher in adult cattle with lymphosarcoma (100% incidence) and in cattle herds with many cases of lymphosarcoma (92-98% incidence). Herds into which cattle from herds including lymphosarcomatous animals had been introduced showed a 35% incidence of BSV infection.

- 1877 ISOLATION OF C-TYPE VIRUS PARTICLES FROM LEUKEMIC AND LYMPHOCYTIC CATTLE. (E.) Dutta, S. K. (Coll. Vetr. Med., U. Minnesota, St. Paul), V. L. Larson, D. K. Sorensen, V. Perman, A. F. Weber, R. F. Hammer and R. E. Shope, Jr. *Bibl Haemat* 36:548-554, 1970.

Electron microscopic studies were carried out on the lymphocytes of cattle with leukemia and lymphocytosis to detect C-type virus particles in these cells. Lymphocytes from the affected animals, and from normal controls, were cultured and stimulated with phytohemagglutinin. Virus particles were observed in 72 hr phytohemagglutinin stimulated lymphocyte cultures; cultures with many immature lymphocytes had more virus particles. Particles were C-type, 100-110 mμ in diameter, and often were seen in the vicinity of cytoplasmic processes of lymphocytes. Particles were isolated from 5 of 7 leukemic cows and from 5 of 5 lymphocytotic cows; no particles were found in normal cows.

- 1878 RNA-DEPENDENT DNA POLYMERASE ACTIVITY IN VIRUS-LIKE PARTICLES ISOLATED FROM HUMAN MILK. (E.) Schlom, J. (Coll. Phys. Surg., Columbia U., New York, N. Y.), S. Spiegelman and D. Moore. *Nature* 231(5298):97-100, 1971.

Milk from American women with and without a familial history of breast cancer was examined for RNA-dependent DNA polymerase activity. Thirteen milk samples examined for type B particles and corresponding RNA-dependent DNA polymerase assays showed a positive correlation between the presence of these virus-like particles and the presence of polymerase activity.

- 1879 THE RATE OF CHROMOSOMAL ABERRATIONS IN HUMAN PERIPHERAL LYMPHOCYTES AFTER VACCINATION WITH VACCINIA-VIRUS *IN VIVO* AND *IN VITRO*. (Ger.) Baldauf, W. (Bavarian Immun. Inst., Munich, Germany), B. Stenglein, I. Unglaub-Leisten, H. Bulheller and H. Stickl. *Klin Wschr* 49(5):260-263, 1971.

Chromosomal abnormalities were induced in PHA-stimulated human lymphocytes from peripheral blood by inoculation of the cultures with vaccinia virus in concentrations of 10^4 and 10^5 plaque forming units/ml. Seven days after virus treatment, adult blood showed significantly increased numbers of chromosomal aberrations including chromatid aberrations, structural aberrations, deletions and dislocations. By 6 months after virus treatment, frequencies of chromosomal aberrations had returned to normal. Lymphocytes from children also showed increased incidence of chromosomal aberrations following vaccinia virus infection of cells *in vitro*; by 7 days after infection, chromosome aberrations had increased 100% over control.

- 1880 EVIDENCE FOR A VIRUS IN HUMAN SARCOMAS. (E.) Morton, D. L. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), F. R. Eilber, R. A. Malmgren and K. O. Cooke. *Bibl Haemat* 36:754-760, 1970.

Sera from sarcoma patients bearing a high titer of antisarcoma antibody were tested by complement fixation against a variety of tissue culture cells from normal and malignant human tissues. Sarcoma specific antigens were found in 10 of 11 cultures established from human sarcomas including osteosarcomas, liposarcomas, fibrosarcomas and synovial cell sarcomas. Most sarcomas had antigen titers of 1/40-1/160. Only 1 of 5 normal cell cultures contained sarcoma specific antigen. When sera from patients with sarcoma and their relatives, and normal sera were tested by complement fixation using antigen prepared from a liposarcoma, 95% of the patients with skeletal or soft tissue sarcomas had antibody to the liposarcoma antigen; only 20% of sera from normal subjects had this antigen. Antibody titers in relatives of sarcoma patients were intermediate between titers in sarcoma patients and titers in controls.

- 1881 CHARACTERIZATION OF DNA ISOLATED FROM METAPHASE CHROMOSOMES OF CELLS CONTAINING EPSTEIN-BARR VIRUS. (E.) Ludwig, H. (Baylor Coll. Med., Houston, Texas), N. Biswal and M. Benyesh-Melnick. *Biochim Biophys Acta* 232(2):261-270, 1971.

DNA was extracted from chromosomes isolated and fractionated from Burkitt's lymphoma cells grown in Eagle's medium supplemented with 20% fetal bovine serum; 5-10 μ g/ml of colcemide was added during the logarithmic growth phase. After 18 hr of incubation with colcemide, the fractions were pooled separately into 3 groups according to chromosome size. Thermal denaturation of DNA's from total chromosomes, chromosome fractions and interphase nuclei yielded a midpoint transition (T_m) in the range of 84-85°; these values corresponded to G+C contents of 36-38%. The nucleotide composition of the DNA from the fractionated chromosomes and the extrachromosomal DNA did not vary significantly from each other. The DNA of the total cell had a buoyant density of 1.698 g/cm³ which did not differ significantly from nuclear DNA of these cells treated with colcemide. However,

centrifugation revealed a small DNA peak with a buoyant density of 1.723 g/cm³ corresponding to a G+C content of 66% in 3 of 7 experiments; this peak represented 2-3% of the bulk chromosomal DNA and the highest amount was present in the small chromosomes. The density of this additional DNA corresponded to the value for DNA extracted from herpes simplex viral DNA which had a density of 1.725 g/cm³; this DNA may represent the Epstein-Barr virus DNA.

- 1882 EB VIRUS INFECTION AND PROPAGATION IN HUMAN HEMATOPOIETIC CELLS. (E.) Horoszewicz, J. S. (Roswell Park Mem. Inst., Buffalo, N. Y.), V. C. Dunkel, L. Avila and J. T. Grace, Jr. *Bibl Haemat* 36:722-738, 1970.

Epstein-Barr virus (EBV) was introduced into cultures of EBV-free cells from a human with myelogenous leukemia; the enveloped virus particles attached quickly to the cells; 8-12 hr after infection, viruses penetrated cell membranes in the manner of herpes simplex virus. Human leukemic cells were infected with low doses of EBV to establish a virus carrier state; a good correlation was found for concentration of virus and decline of viability in infected cultures. A virus carrier state was established in 45 cultures of EBV-free human leukemic cells and maintained for periods up to 2.5 yr. When hematopoietic cell lines from normal humans were infected with EBV, cell death ensued within 5 days postinfection with high concentrations of virus. In cultures infected with lower virus concentrations, virus-producing cells gradually disappeared. Sera which gave positive immunofluorescent reactions to EBV neutralized the virus; however, these sera did not impair the infection of cells already chronically infected with EBV. Infection with EBV resulted in the appearance of a new antigen on the surface of infected cells.

- 1883 LYMPHOPROLIFERATIVE EFFECT OF EPSTEIN-BARR VIRUS ON NORMAL HUMAN LYMPHOCYTES IN CULTURES. (E.) Gerber, P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), J. Whang-Peng and J. H. Monroe. *Bibl Haemat* 36:739-750, 1970.

Leukocyte cultures were prepared from blood of a 21-yr-old male with no evidence of the presence of herpes viruses; viable cells disappeared from cultures at 50-65 days of cultivation. When the growth of virus-free cultures was compared with the growth of cultures infected with Epstein-Barr virus (EBV), it was found that virus-free cultures and cultures treated with EBV neutralized with EBV-positive human serum antibodies continued to lose viable cells after 21 days in culture, while cultures treated with non-neutralized EBV continued to proliferate and showed the development of macroscopic cell clusters. Virus-transformed cultures contained about 12% small lymphocytes, 70% medium-sized lymphocytes and 14% large lymphocytes; all lymphocytes had large nuclei and sparse cytoplasm. Virus-free cultures and cultures containing neutralized EBV failed to stain in immunofluorescence tests, while 10-15% of the

cells of EBV-infected cultures stained by about 6 wk in culture. Chromosome analysis of virus-free cultures showed that phytohemagglutinin-stimulated cells had the normal male karyotype with 2% breaks and 0.5% polyploidy. Virus-transformed cultures showed hyperploidy, the number of cells having 47-49 chromosomes increasing with time in culture.

- 884 INDUCTION OF CELLULAR DNA SYNTHESIS IN HUMAN LEUCOCYTES BY EPSTEIN-BARR VIRUS. (E.) Gerber, P. (Div. Biol. Standards, Natl. Inst. Hlth., Bethesda, Md.) and B. H. Hoyer. *Nature* 231(5297):46-47, 1971.

Leukocytes were prepared from heparinized blood of healthy adults and treated in culture with *Candida albicans* allergenic extract, UV radiation-inactivated or heat-inactivated Epstein-Barr virus (EBV), or viable EBV. From 3-12 days in culture, leukocyte DNA synthesis, as measured by uptake of ³H-thymidine, had increased from 3 to 63 cpm/(culture 10⁻³) in cultures treated with viable virus. In control cultures and cultures treated with inactivated virus, uptake of labeled thymidine remained near 3 cpm/(culture 10⁻³) throughout the duration of the experimental period. In cultures treated with *C. albicans* extract, tritiated thymidine uptake dropped from 127 to 20 cpm/(culture 10⁻³) between days 3 and 12. The ³H-thymidine incorporated into acid precipitable components in cells stimulated by EBV was predominantly non-viral, and the stimulation of cellular DNA synthesis by EBV was regarded as significant and unusual.

- 885 CYTOGENETIC STUDIES OF EB VIRUS-POSITIVE AND EB VIRUS-NEGATIVE LYMPHOBLASTOID CELL LINES. (E.) Macek, M. (Inst. Child Develop. Res., Charles U., Prague, Czechoslovakia), E. H. Seidel, J. T. Lewis, J. P. Brunschwig, I. Wimberly and M. Benyesh-Melnick. *Cancer Res* 31(3):308-321, 1971.

Sixteen lymphoblastoid cell lines (including 3 lines of Burkitt's lymphoma cells, 3 lines of acute leukemia cells, 8 lines of infectious mononucleosis cells and 2 lines of cells from normal donors) were maintained in culture for periods up to 61 months. Most cells retained a diploid mode with the exception of some infectious mononucleosis cells which developed complete heteroploidy, and some lines from all 4 classes developed hyperdiploidy with 47 or 48 chromosomes. Some of the common types of marker chromosomes were seen in all the 16 lines examined. The most frequent type was marker m₂, an abnormal chromosome similar to chromosome 18 but 34% larger than a normal A₂ chromosome. An abnormal chromosome with the centromere in the subtelocentric region was another frequently observed marker chromosome. Other abnormalities observed included chromosomes with the centromere in the terminal region, and long acrocentric chromosomes. An increased proportion of chromosomes with trisomy C was found in 11 of the 16 cell lines, with trisomy D and G also observed, but less often. Cells with marker chromosomes or trisomies appeared with increasing frequency in clones

of cultured cell lines, indicating that cells with these features have a selective advantage for growth *in vitro*. Epstein-Barr virus was found in cells from all of the 3 Burkitt's lymphoma lines, in 1 of the acute leukemia lines, and in 5 of the infectious mononucleosis lines. No virus was found in normal cell lines, and there did not appear to be a correlation between the presence of virus and any of the observed chromosomal features of the cell lines. Subterminal constrictions of the long arms of group C chromosomes were found in all but 1 cell line.

- 1886 STUDIES OF EPSTEIN-BARR VIRUS (E.) Grace, J. T., Jr. (Roswell Park Mem. Inst., Buffalo, N.Y.). *Ann NY Acad Sci* 174(2):946-966, 1970.

Continuing experiments are described in which clones of Burkitt lymphoma cells are examined for the presence of Epstein-Barr virus (EBV); a correlation was found between percent of fluorescent cells in immunofluorescence tests and percent of virus-containing cells; less than 3% of the cells drawn from a culture with 1% fluorescent cells contained virus, and 69% of the cells drawn from a culture having 75% fluorescent cells contained virus. Burkitt cells produced the fewest virus when cultured in regular growth medium at 37°; maximum virus counts were seen when cells were cultured at lower temperatures. Virus from these cells were usually solitary and only occasionally appeared in groups. Relatively few particles had envelopes. It was found that more than 90% of sera obtained from normal adults in the United States gave positive immunofluorescence when tested against virus-containing cell lines. Infectivity of EBV was found to rise with dose of virus, and infection resulted in severe cell damage with the appearance of a new antigen at the surface of infected cells. The progress of EBV infection resembled that of herpes simplex virus infection. No sign of infection could be detected when EBV was inoculated into cultures of various nonhuman cell systems.

- 1887 MINOR RNA AND OTHER COMPONENTS OF HOST ORIGIN INTRINSIC TO AVIAN LEUKOSIS VIRUS PARTICLES. (E.) Bolognesi, D. P. (Max Planck Inst. Virus Res., Tübingen, Germany) and T. Obara. *Bibl Haemat* 36:126-139, 1970.

Concentrated virus from leukemic plasma and labeled virus from tissue culture fluids were layered on a 20-50% discontinuous sucrose gradient, fractionated and assayed for optical density, radioactivity, and RNA analysis. The RNA pattern following isolation from a purified avian myeloblastosis virus preparation revealed a minor component sedimenting between the 60S and 4-5S RNA while fractionation of RNA from the latter co-sedimented with those of the former which were previously shown to co-sediment with ribosomal RNA. Ribonuclease treatment had little effect upon the proportion of 26S and 16S RNA and the base ratio analysis indicated that the viral and analogous cell components had corresponding base composition with a higher G-C content in the 26S ribosomal RNA.

- 1888 EVIDENCE FOR THE VERTICAL TRANSMISSION OF 'NON-INFECTIOUS' AVIAN LEUKOSIS VIRUS IN 'LEUKOSIS-FREE' CHICKENS. (E.) Sarma, P. S. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), F. Edwards, R. J. Huebner, H. C. Turner and L. Vernon. *Bibl Haemat* 36:168-182, 1970.

Chick embryo liver cells prepared from material taken from "leukosis-free" flocks of white leghorn chickens were tested by complement-fixation studies for the presence of complement fixing antigens and for the presence of infectious leukosis virus. Of 138 embryo liver cell samples tested, 53 gave complement fixing reactions positive for an antigen similar to the avian leukosis group specific antigen. Infectious avian leukosis virus was recovered from chick embryo liver fibroblast cultures but not from quail embryo liver fibroblast cultures. Virus isolated from chick embryo liver fibroblast cultures appeared to be identical to Rous-associated virus group 1. While liver samples from embryo derived from virus-transmitting hens failed to yield infectious virus, many of these same samples yielded ether-resistant complement fixing antigen. Chicken embryo liver antigens were found to be of 2 types: an ether-resistant antigen similar to the leukosis group specific antigen, and an ether-labile antigen which was probably a chicken isoantigen. Apparently a non-infectious avian leukosis virus is transmitted vertically or, alternatively, an infectious virus which has an extremely limited host range is transmitted.

- 1889 ENHANCING THE SUSCEPTIBILITY OF CHICKS TO MYELOID LEUKAEMIA VIRUS BY MYELOID-CELL STIMULATION. (E.) Lagerlöf, B. (Karolinska Hosp., Stockholm, Sweden). *Acta Path Microbiol Scand* 79(2): 208-209, 1971.

One-day-old chicks were given i.p. injections of 1×10^4 staphylococci; chicks developed acute peritonitis. Of the chicks injected with staphylococci, some were given a subsequent injection of pure or diluted BAI strain of myeloid leukemia virus. Chicks injected with staphylococci developed a higher incidence of leukemia after a shorter elapsed time from the injection of virus than did chicks injected with virus with no staphylococci pretreatment. Undiluted leukemia virus produced a 75% incidence of leukemia among pretreated chicks and a 40% incidence in untreated chicks on day 35 after virus inoculation. No difference in the severity of the leukemia developed by the staphylococcus-virus and the virus only group was found. The enhancing effect of staphylococcus infection on leukemogenesis was apparently due to the stimulation of the myeloid cells by the staphylococcus.

- 1890 TRANSMISSION OF AVIAN MYELOBLASTOSIS BY BAI STRAIN A VIRUS RIBONUCLEIC ACID. (E.) Veprek, L. (Duke U. Med. Ctr., Durham, N. C.), D. Beard, A. J. Langlois, R. Ishizaki and J. Beard. *J Natl Cancer Inst* 46(4):713-729, 1971.

Pellets prepared by centrifuging BAI strain A virus were treated with sodium dodecyl sulfate and dithio-

threitol to isolate the viral RNA, and high molecular wt RNA was used to infect chick embryo cells cultured with DEAE-dextran. Two of 5 RNA preparations induced infection, morphologic alteration, and liberation of virus by infected chick cells; a third preparation induced infection and synthesis of virus in cells but produced only 1 case of myeloblastosis when inoculated into newborn chicks. The other cell cultures infected with RNA preparations produced virus which, when inoculated into chicks, caused a characteristic BAI virus infection marked by myeloblastosis, and ovarian, renal and hepatic tumors. Nephroblastomas were also developed in some chicks. Virus produced by viral RNA-infected cultures transformed fresh chick embryo cells but did not transform bone marrow cells. RNA preparations inducing infection apparently contained no virus particles; the infection of chick cells by RNA could be prohibited by ribonuclease treatment. The infectious agent from BAI-RNA infected chick cells induced liberation of infectious virus in non-producer Rous sarcoma virus cells and interfered with Rous sarcoma virus and MC29 virus focus formation.

- 1891 VIROLOGICAL ANALYSIS OF INDIVIDUAL FOCI INDUCED IN HEMATOPOIETIC CELLS BY AVIAN MYELOBLASTOSIS VIRUS. (E.) Moscovici, C. (VA Hosp., Gainesville, Fla.). *Bibl Haemat* 36:148-152, 1970.

Chick embryo yolk sac cultures were infected with avian myeloblastosis virus of subgroups A and B. Foci of infected cells yielded myeloblasts containing virus; these myeloblasts induced cell transformation *in vitro* and leukemia in birds inoculated with them. Another group of cells produced foci which released myeloblastosis-associated virus; myeloblasts from these foci did not transform cells *in vitro*. When injected into living chick embryos, these cells did not produce leukemia, but did produce adenocarcinoma. Only 1 focus of 20 gave rise to infectious progeny after infection of yolk sac cultures with avian myeloblastosis virus subgroup B; cells from this focus had transforming ability and produced leukemia in inoculated birds. Virus-free foci were challenged with a variety of leukosis viruses including Rous-associated virus and myeloblastosis-associated virus and transforming avian myeloblastosis virus was rescued in some cases.

- 1892 DEOXYRIBONUCLEIC ACID POLYMERASE ACTIVITY ASSOCIATED WITH STRAIN MC29 TUMOR VIRUS. (E.) Weber, G. H. (Dept. Agric. Chem., Oregon St. U., Corvallis), A. A. Kiessling and G. S. Beaudreau. *J Virol* 7(2):214-220, 1971.

The presence of a DNA polymerizing activity in strain MC29 tumor virus was studied in infected chick embryo cells utilizing deoxyribonucleoside triphosphates and calf thymus DNA. DNA directed reactions had a 10-fold greater rate of ^3H -thymidine triphosphate incorporation compared to endogenous reactions; a strong depression in rate resulted from the omission of dATP and dCTP and a lesser depression was seen with the omission of dGTP. The enzyme preparation from

29 virus incorporated ^3H -dGTP into DNA at twice the rate of ^3H -TTP incorporation, whereas enzyme from avian myeloblastosis virus incorporated ^3H -dGTP at about 3 times the rate of ^3H -TTP incorporation. DNA synthesis with the MC29 virus preparation without added template showed only slight DNA synthesis relative to the activity when DNA was added. These results demonstrated clearly that a DNA-polymerase activity is associated with MC29 virus infection.

93 DNA POLYMERASE ACTIVITY IN HOMOGENATES OF CELLS INFECTED WITH MC29 VIRUS. (E.) Weber, H. (Dept. Agric. Chem., Oregon St. U., Corvallis), A. Kiessling and G. S. Beaudreau. *Biochem Biophys Commun* 42(6):993-999, 1971.

Chick embryo cells were infected with myelocytomatosis virus (2.8 x 10⁴ focus forming units/culture), and infected and uninfected cells were assayed for DNA polymerase. The enzyme was present in uninfected chick cells, but the activity in virus infected cells was greater than in uninfected cells. The homopolymer dU:dC:poly rG did not stimulate DNA polymerase in uninfected cells; however dC:rG produced a 3-fold stimulation of DNA synthesis in virus-infected cells. DNA from *M. lysisdeikticus* and from avian myeloblastosis virus produced greater DNA synthesis in virus infected cells than in uninfected cells.

94 FELINE LEUKEMIA: CHARACTERIZATION OF THE VIRUS. (E.) Burger, C. L. (St. U. New York, Upstate Med. Ctr., Syracuse), J. L. Olpin, G. Soofi and B. C. Maher. *Bibl Haemat* 36:379-386, 1970.

Line leukemia virus obtained from a cell line derived from a kitten inoculated with feline lymphocytic leukemia was separated by centrifugation and prepared for nucleic acid extraction, chemical determination, RNA and amino acid analysis. The maximum absorbency of the nucleic acid fraction occurred at 260 nm and the minimum at 230 nm; orcinol reactions confirmed the presence of RNA type nucleic acids. The melting profile suggested the RNA was a single-stranded type and it was converted to oligonucleotides by RNase. The buoyant density of the RNA (1.64 g/ml) was calculated by analytical ultracentrifugation; the band width when compared with that obtained in polyoma viral nucleic acid indicated a molecular wt of at least 1 x 10⁶. Electrophoretic migrations ranged from 45 min to 3 hr and cells labeled with tritiated uridine showed label exclusively in the nucleus after 1 hr, while later stages showed filtration into the cytoplasm. Not all cells at 1 time periods produced reasonable data.

95 GROWTH OF FELINE LEUKEMIA VIRUS IN HUMAN, CANINE AND PORCINE CELLS. (E.) Jarrett, (Anim. Leukemia Res. Unit, U. Glasgow, Scotland), M. Laird and D. Hay. *Bibl Haemat* 36:387-392, 1970.

Line leukemia virus (FeLV-5) was isolated from a cat with spontaneous alimentary lymphosarcoma and

maintained in cultures of feline embryonic cells. The virus was inoculated into cultures of porcine and canine kidney cells and human embryonic lung cells; the virus was found to be replicating in all recipient cell cultures by electron microscopy in the third wk after FeLV-5 infection. Complete viral particles with the character of leukemia viruses were seen in extracellular spaces in human cell cultures, and incomplete particles were seen budding from cell membranes. FeLV-5 did not appear to grow in bovine, murine, rat or chicken cells. Growth of virus was also demonstrated in human lung embryo cells by the incorporation of ^3H -uridine into purified virus from culture fluids.

1896 REPEATED DEMONSTRATION OF A MOUSE LEUKEMIA VIRUS AFTER TREATMENT WITH CHEMICAL CARCINOGENS. (E.) Ball, J. K. (Cancer Res. Lab., U. Western Ontario, London, Canada) and J. A. McCarter. *J Natl Cancer Inst* 46(4):751-762, 1971.

Although untreated CFW/D mice developed thymic lymphomas in only 0.12% of cases, the incidence of thymic tumors among mice given a thymic injection of cell-free filtrate from a 7,12-dimethylbenz(a)anthracene (DMBA)-induced thymic lymphoma was 73%; tumors induced by lymphoma cell-free filtrates had short latent periods (161 days average). When heavily (20,000 or 40,000 rads) irradiated tumor cell supernatants were injected into irradiated mice containing 7-day-old intrarenal thymus grafts, supernatants from 9 of 11 DMBA-induced lymphomas produced tumors in recipients. The supernatant from one of these tumors borne by a thymic grafted mouse, when injected into other mice, produced 7 tumors in 9 mice. Most tumors in thymic graft-bearing mice involved the grafted thymus only; irradiated supernatant was usually injected directly into the thymic graft. No significant leukemogenic activity was noted for thymus, bone marrow or liver taken from normal mice; thymus graft tumors did develop in 4 of 54 mice given whole-body irradiation and an intrarenal thymic graft. Seven days after a neonatal injection of DMBA, bone marrow and liver preparations from treated mice developed thymic lymphomas with low incidences. With serial animal passage, the tumor incidence increased and latency shortened. Thymic lymphomas could also be induced by injecting thymic grafted mice with supernatants from DMBA-induced fibrosarcomas and methylcholanthrene-induced fibrosarcomas. A thymic lymphoma, induced by passage of cell-free material from a DMBA-induced tumor, yielded a filtrate which could rescue the murine sarcoma virus genome present in Moloney sarcoma virus-induced hamster tumor cells.

1897 HEMOGLOBIN SYNTHESIS IN MURINE VIRUS-INDUCED LEUKEMIC CELLS IN VITRO: I. PARTIAL PURIFICATION AND IDENTIFICATION OF HEMOGLOBINS. (E.) Scher, W. (Mount Sinai Sch. Med., City U. New York, N. Y.), J. Gilbert Holland and C. Friend. *Blood* 37(4):428-437, 1971.

After at least 3 biweekly passages in medium containing radioactive iron, smears were prepared from cloned cultures of a mass-cultured Friend virus-

induced leukemic cell line, designated C-1A which had been in serial passage for over 4 yr. Iron accumulation and heme biosynthesis were assayed by the method of Krantz and Fried. Iron accumulation continued for 4 days in a cloned line (III-1) which produced a relatively high percentage of benzidine-positive cells, but it ceased to accumulate in the parent cells, C-1A, after 40 hr. When the rate of iron incorporation into heme in these 2 cell lines was compared, the difference became more striking. A rapid rate of iron incorporation into III-1 cells was maintained for 4 days, but ceased by the second day in C-1A cells. Hemoglobin isolated from 2 cloned lines after 72 hr of growth was resolved into 3 components on 10% polyacrylamide gel electrophoresis. The electrophoretic pattern of these 3 hemoglobins appeared similar to that of hemolysates of adult DBA/2J mice, from which the cells originated.

- 1898 STUDIES ON FRIEND VIRUS-INDUCED VIREMIA IN LETHALLY IRRADIATED MICE WITH OR WITHOUT HEMATOPOIETIC REPOPULATION. (E.) Rossi, G. B. (Mt. Sinai Sch. Med., City U. New York, N.Y.), E. De Harven, J. R. Haddad and C. Friend. *Int J Cancer* 7(2):303-312, 1971.

The effect of repopulating lethally irradiated ICR/Ha Swiss and DBA/2J mice with normal cells on Friend virus-induced viremia was studied in spleen and thymus cells under the electron microscope. Virus titers in the plasma of non-irradiated controls reached expected levels from day 4 on, while no appreciable amount of virus was recovered from the plasma of irradiated mice. Pellets from controls contained large populations of typical virus particles of the C and A type, whereas those from irradiated mice showed a variety of minute cell debris and platelet granules but no clearly identifiable virus particles. Viral replication in lethally irradiated mice inoculated with spleen cells and bone marrow was seen as confluent colonies in the spleen by the 10th day with only rare minute-sized colonies appearing in thymus cell-inoculated animals, including both erythroid and myeloid components. These data suggest that Friend leukemia virus replication is not supported by recipient mice deprived of practically all of their hematopoietic cells.

- 1899 INFLUENCE OF SENSITIZATION WITH BACTERIAL ANTIGENS ON THE REPLICATION OF FRIEND SPLEEN FOCUS-FORMING VIRUS. (E.) Flickinger, J. T. (C.H.U., U. Sherbrooke, Quebec, Canada) and J. M. Gentile. *Canad J Microbiol* 17(4):481-486, 1971.

Female mice of strain HA/ICR were given i.p. injections of 25 µg of O and H antigens prepared from *Salmonella typhosa* or *Proteus mirabilis*; the bacterial antigens were administered either 5 or 3 days before infection of mice with Friend virus, or simultaneously with virus infection, or 3 days after virus infection. Mice sensitized with *S. typhosa* antigens 5 days prior to virus infection showed an enhanced rate of Friend virus replication in the spleen com-

pared to mice sensitized 3 days before or 3 days after virus infection. On day 14 after virus infection, foci per spleen counts in mice given *S. typhosa* antigen 5 days before infection were increased over counts for mice given antigen 3 days before and 3 days after infection. The foci per spleen counts for mice in the latter 2 groups were similar to those recorded for mice not treated with bacterial antigen. In mice which were given both Friend virus and bacterial antigen simultaneously, virus replication was seen to be inhibited by day 14 postinfection. Treatment of mice with the H or flagellar antigen prepared from *P. Mirabilis* did not affect the replication of Friend virus in these mice, regardless of the time at which the antigen was administered relative to the time of virus infection.

- 1900 DEFECTIVE FRIEND SPLEEN FOCUS-FORMING VIRUS PSEUDOTYPE NEUTRALIZATION BY HELPER-SPECIFIC ANTISERA. (E.) Eckner, R. (Dept. Exp. Biol., Roswell Park Mem. Inst., Buffalo, N. Y.) and R. A. Steeves. *Nature* 229(8):241-243, 1971.

Spleen focus-forming virus was prepared from splenic homogenates of Friend virus-infected Ha/ICR swiss mice and injected into the lateral tail veins of untreated animals and of animals treated with 2 mg of hydrocortisone injected i.p. 9 and 8 days before infection and 1 mg 7 and 6 days before infection. The spleen focus-forming virus maintained in Swiss mice routinely gave single-hit dose-response titration patterns in susceptible hosts, but multiple hit patterns in BALB/c mice and other partially resistant strains. In treated mice, the injection dose-response curve shifted upward with no change in slope from that obtained with untreated mice. Upon co-infection with the 334C virus of Buffte and a lymphatic leukemia virus, the titers of the spleen focus-forming virus were greatly increased and the most elevated titers at the greatest dilution changed the slopes of the dose-response curves to a single hit form. In the presence of sera from Swiss mice given 10 weekly i.p. injections of Swiss lymphoma cells induced by a helper virus and leukemia virus, altered antigenicity of the spleen focus-forming virus pseudotypes resulted.

- 1901 NUCLEOSIDE DEAMINASE ACTIVITY IN VIRAL LEUKEMIA. (E.) Rothman, I. K. (New York U. Sch. Med., New York, N.Y.), V. G. Malathi and R. Silber. *Cancer Res* 31(3):274-276, 1971.

Swiss-Webster and BALB/c mice were inoculated with preparations of Friend leukemia virus, Rauscher leukemia virus, or Moloney virus and homogenates prepared from their spleens were examined for nucleoside deaminase activity measured by the amount of radioactively-labeled uridine formed by the deamination of ¹⁴C-labeled cytidine. A 10-fold increase in spleen wt was seen 5 days after infection with Friend virus. Control mice not injected with virus showed spleen nucleoside deaminase activity levels ranging from 2.6-3.8 milliunits/g spleen tissue. Nucleoside deaminase activity of mice infected with Friend virus was at 1013.0 milliunits/g by 8 days

postinfection, and nucleoside deaminase activity in mice infected with Rauscher virus was at 389 milliunits/g by 18 days postinfection. Administration of 50 mg phenylhydrazine in the absence of viral infection elevated nucleoside deaminase activity to 294 milliunits/g by 4 days after injection of phenylhydrazine. Infection with Moloney virus produced nucleoside deaminase levels of 6.5 milliunits/g by 5 days postinfection. The erythroid nature of the disorders induced by Friend and Rauscher viruses may be related to the elevated nucleoside deaminase activity.

02 PROPERTIES OF TRANSFORMED HEMOPOIETIC CELLS IN MICE INFECTED WITH THE FRIEND VIRUS COMPLEX. (E.) Steeves, R. A. (Roswell Park Mem. Inst., Buffalo, N.Y.), E. A. Mirand and S. Thomson. *Bibl Haemat* 36:624-633, 1970.

Young adult BSF₁ hybrid mice were injected i.v. with Friend virus-infected Swiss inbred mice spleen cells; after the injection the spleen cells from the hybrid primary recipients were suspended in medium and assayed for tumor colony forming units in hybrid secondary recipients. Ten days after injection, the frequency of tumor colony forming units was one per 10⁴ spleen cells with a decline noted during the next 10 days, while total cell count per spleen rose slowly. To demonstrate the presence of a neoantigen on Friend virus-induced tumor colony forming units, BSF₁ mice were injected i.p. 20 or 4 days before cell challenge with normal Swiss inbred mice spleen cells, cellular antigen from Friend virus-infected and normal Swiss inbred mice, or Friend virus complex. Nine days after challenge with Friend cells, the only groups which showed significant transplantation immunity were those injected with cellular antigen from virus-infected mice or with an ether-extracted Friend virus complex. γ-irradiated Friend virus complex failed to induce this immunity.

03 EFFECT OF BCG ON FRIEND DISEASE VIRUS IN MICE. (E.) Larson, C. (Dept. Microbiol., U. Montana, Missoula), R. Ushida, M. Florey, R. Baker and M. Baker. *Nature* 229(53):243-244, 1971.

Sixty-five female mice were infected with Friend disease virus (FDV) by i.v. injection of 0.3 ml of virus preparation; 31 of the mice had, 3 wk previously, been immunized with *Mycobacterium bovis* (BCG). After 4 wk, FDV-infected mice had pronounced splenomegaly compared to BCG-immunized mice. At 8.5 wk postinfection, 50% of the unimmunized mice and 23% of the immunized mice had died; mortality at 12.5 wk among immunized and unimmunized mice was 50% and 90%, resp. In a related experiment, male mice were immunized with BCG and later challenged with FDV. Sixteen wk after infection, mortality in immunized and unimmunized mice was 50% and 100%, resp. It is believed that the effect of BCG vaccination on subsequent FDV infections is based on nonspecific cellular immunity.

1904 THE ROLE OF GENETICS IN GROSS VIRUS LEUKEMOGENESIS. (E.) Lilly, F. (Albert Einstein Coll. Med., Bronx, N. Y.). *Bibl Haemat* 36:213-220, 1970.

Hybrid (BALB x C57BL) x BALB backcross generation mice and mice of the (B10.BR x C57BL) x N10.BR backcross generation inoculated with Gross virus and typed for the histocompatibility-2 locus of the 9th chromosome were observed for leukemia incidence. Heterozygous H-2^b/H-2^d mice among the first hybrids showed a lower incidence of leukemia among 2 groups with values of 3% and 37% compared to their homozygous H-2^d/H-2^d littermates with values of 44% and 76%. Among the second hybrids the H-2^k/H-2^k segregants showed a leukemia incidence that was consistently higher and occurred sooner than that among heterozygous H-2^k/H-2^b segregants; however, the difference between the 2 classes of mice appeared greater when virus preparations of lower potency were used than when high-titer preparations were used. The incidence of leukemia induced by Gross virus among mice of various strains indicated a significantly greater susceptibility to leukemogenesis among BALB/c strain mice than mice of the A strain and presented a more complex association between the histocompatibility locus and leukemogenesis.

1905 STUDIES ON HYPODIPLOID AND HYPERDIPLOID VIRUS-INDUCED MOUSE LEUKEMIAS AND THE VERTICAL TRANSMISSION OF MSV-MOLONEY. (E.) Ida, N. (Toyo Kogyo Hosp., Hiroshima, Japan), Y. Ikawa and Y. Ohba. *Bibl Haemat* 36:221-233, 1970.

Thirty-nine C3H mice were examined from the 3rd through the 16th transplant generation of Moloney virus-induced mouse leukemia with a high percentage of the cells derived from their thymuses, spleens, mesenteric lymph nodes and livers showing predominantly 39 acrocentric chromosomes compared to the 40-chromosome complement of the control tissue. New-born Swiss mice inoculated at birth with cell-free supernatants of murine virus-induced sarcomas harvested before the 30th day of culture revealed development of sarcomas in 100% of 34 recipients, while supernatant of a 33-day culture produced sarcomas in only 41% of the recipient hosts with latent periods of 85 days. In addition, leukemias developed in 29.4% of the mice, revealing a hyperdiploid stemline with 41 chromosomes. Pregnant Swiss ICR mice repeatedly injected i.p. with murine sarcoma virus or with murine sarcoma virus and Moloney leukemia virus developed no tumors when virus-injection was initiated before or soon after the placenta was established or at the 9th day of gestation. One recipient of both viruses on the 13th gestation day developed a sarcoma after a latent period of 20 days and all recipient hosts receiving tissue culture fluid from this passage developed sarcomas.

1906 DECREASE IN TUMOR-PRODUCING CAPACITY OF MOUSE CELL LINES FOLLOWING INFECTION WITH MOUSE LEUKEMIA VIRUSES. (E.) Barbieri, D. (Inst. Gustave Roussy, Villejuif, France), J. Belehadek, Jr. and G. Barski. *Int J Cancer* 7(2):364-371, 1971.

Cell lines from C57BL/6 mice treated with 3-methylcholanthrene (3-MC) and from mice in which spontaneous tumors arose were infected in culture with Rauscher leukemia virus of a highly leukemogenic strain (RRL⁺) or with Rauscher virus of a mildly leukemogenic strain (RCL⁻). While both the 3-MC-treated mouse cells and the spontaneously-transformed mouse cells alone produced tumors in syngeneic mice, the tumorigenicity of these cells was seen to decline following *in vitro* infection with Rauscher virus. When injected into mice, the virus-infected spontaneously-transformed cells produced tumor takes in 23-54% of cases as compared to 100% takes observed for non-infected spontaneously transformed cells. Latency of tumor appearance in mice inoculated with spontaneously transformed cells increased from 35 days to 164-165 days upon infection of the cells with Rauscher virus. When Rauscher virus-infected spontaneously transformed cells were inoculated into mice which had been pre-immunized by prior injection of the same cell and subjected to whole-body X-irradiation (400 r), 73% of the irradiated but unimmunized mice developed tumors; none of the immunized and irradiated mice developed tumors. Mice inoculated with cells from 3-MC-treated tumor bearing mice developed tumors in 100% of the cases, but mice inoculated with 3-MC-transformed cells infected with RRL⁺ or RCL⁻ virus did not develop tumors. In all cells infected with Rauscher virus C-type virus particles appeared in the infected cell cultures; a surface antigen reacting with anti-Rauscher virus serum also appeared in virus-infected transformed cells. When spontaneously-transformed mouse cells were treated with 3-MC, C-type particles and an anti-Gross leukemia virus surface antigen were observed in the cultures. Treatment of spontaneously-transformed cells with 3-MC produced cells which were less tumorigenic than untreated transformed cells.

- 1907 ENZYME STUDIES IN EXPERIMENTAL LEUKEMIA. (E.) Cory, J. G. (Dept. Chem., U. South Florida, Tampa) and M. A. Rich. *Bibl Haemat* 36:267-277, 1970.

The content in mouse liver, spleen and thymus of enzymes involved in the degradation of nucleic acids was altered in mice infected with Rauscher or Rich leukemia viruses. Enzymes were assayed in normal and virus-infected organs at 3, 6 and 14 days after inoculation of virus, and results were expressed as the ratio of specific enzyme activities. In the spleen, aspartyl transcarbamylase (ATCase) activity was increased in Rauscher-infected mice, ratios of enzyme in infected and normal mice being 1:30 and 3:0 on day 6 and 14, resp. RNase and alkaline phosphatase activity were reduced in spleens of Rauscher virus-infected animals. ATCase increased 10-fold in Rauscher-infected mouse thymus by 3 days postinfection; infected mouse thymus also showed 3-fold increases in acid RNase and in phosphodiesterase. Rich virus infection also produced similar changes in thymus, liver and spleen enzyme activities.

- 1908 HIGH AND LOW LEUKEMOGENIC VARIANTS OF RAUSCHER VIRUS HAVING A COMPARABLE INFECTIVITY *IN VITRO*. (E.) Barski, G. (Inst. Gustave

Roussy, Villejuif, France). *Bibl Haemat* 36:323-326, 1970.

Cell lines derived from lung tissue of adult C57BL mice were infected with variants of Rauscher leukemia virus having high (Le⁺) and low (Le⁻) leukemogenicity. Both virus variants produced C-type virus particles in transformed cells, and both variants showed similar indices of specific cell immunofluorescence. The 2 variants performed alike in specific cytotoxicity tests. Dilutions of Le⁺ and Le⁻ variants were of similar infectivity *in vitro*. However, when cultures of Le⁺ and Le⁻ virus were subjected to ultracentrifugation and their supernatants inoculated into newborn BALB/c mice, Le⁺ supernatants produced leukemias in nearly all inoculated animals, while Le⁻ supernatants gave no leukemias, the difference in leukemogenic potential between Le⁺ and Le⁻ viruses amounting to 5 logs. Apparently, the attenuation of the leukemogenic properties of Le⁻ virus was not due to the lowering of virus production in cultures infected with this virus variant, nor to a decline in cell infectivity of Le⁻ but was due to an inherent low pathogenic potential.

- 1909 TESTS FOR MOUSE LEUKEMIA VIRUSES AND ISOLATION OF SOME OF THEIR COMPONENTS. (E.) Schäfer, W. (Max Planck Inst. Virus Res., Tübingen, Germany), J. Szanto, F. A. Anderer, H. Frank, H. Gelderblom, J. Lange and L. Pister. *Bibl Haemat* 36:327-332, 1970.

A group-specific antigen was isolated from Friend and Rauscher murine leukemias by complement fixation tests the specific activity of the antigen was very high, corresponding to 10⁻⁹ to 10⁻⁸g of protein per positive complement fixation. A hemagglutination reaction, using sheep red blood cells, was produced for the virus only when some host material was removed from the virus by treatment with neuraminidase and phospholipidase C; in the presence of these enzymes, hemagglutination titers of 1,024 were attained. For positive hemagglutination reactions, 3 x 10¹⁰ Rauscher virus particles were needed. The hemagglutinin appeared to be a virus-specific constituent of the murine leukemia virus particles having a type specific antigenic character.

- 1910 EVIDENCE FOR THE RAPID DECREASE IN LEUKEMOGENIC POTENTIAL OF RAUSCHER LEUKEMIA VIRUS IN CELL CULTURE. (E.) Schlom, J. (Coll. Phys. Surg. Columbia U., New York, N.Y.), J. B. Moloney and V. Groshen. *Cancer Res* 31(3):260-264, 1971.

Mice were inoculated with Rauscher leukemia virus and the amount of virus required to produce spleen weight increase (the "effective dose" or ED₅₀) was compared with titers of *in vitro* murine sarcoma helper virus in 6-day Rauscher virus cultures derived from inoculated mice; a constant ratio of about 10 murine sarcoma virus helper units to 1 splenomegaly ED₅₀ unit was found. Quantitative change in the virulence of Rauscher virus, as measured by the increased titers of murine sarcoma helper virus in Rauscher virus cultures, were seen following single passages in culture of Rauscher virus.

Lysates derived from secondary mouse embryo fibroblast cultures 4 and 13 days after inoculation with Rauscher virus showed murine sarcoma virus helper unit titers 6300 times greater than the titers reflecting the leukemogenic activity of the sample (e.g., splenomegaly ED₅₀). Growth curves of Rauscher virus showed production of leukemogenic virus by 2 days postinfection, and maximum production of infectious virus occurred at day 5. By 24 hr postinfection, large quantities of murine sarcoma virus helper could be seen in the cultures. Following 1 passage in culture, the leukemogenicity of Rauscher viruses was seen to decline.

- 1911 INITIATION OF MAMMALIAN VIRAL PROTEIN SYNTHESIS. (E.) Caffier, H. (Inst. Molec. Virol., St. Louis U. Sch. Med., Mo.), H. Raskas, J. Parsons and M. Green. *Nature* 229(8):239-241, 1971.

Cytoplasmic extracts of cultured human cells (KB) infected with human adenovirus type 2 and labeled for 5 min with ³H-methionine were prepared; unlabeled cytoplasmic extracts from KB cells were incubated for 20 min with ³H-methionine for N-terminal amino-acid determination of nascent and released polypeptides. Nascent chains labeled under both conditions contained approximately 25% N-terminal methionine. The methionine incorporated into released proteins both *in vivo* and *in vitro* was 5% N-terminal, suggesting that methionine is an initiator amino-acid for adenovirus structural proteins.

- 1912 STRUCTURAL PROTEINS OF ADENOVIRUS: V. SIZE AND STRUCTURE OF THE ADENOVIRUS TYPE 2 HEXON. (E.) Franklin, R. M. (Wallenberg Lab. U. Uppsala, Sweden), U. Pettersson, K. Akervall, B. Strandberg and L. Philipson. *J Molec Biol* 57(3):383-395, 1971.

The adenovirus type 2 hexon was purified for molecular wt determination by means of sedimentation-diffusion and equilibrium sedimentation (hydrogen exchange with tritiated water); crystal density was determined by means of equilibration between buffer solution and bromobenzene and xylol. The molecular wt range obtained by sedimentation equilibrium (333,000 to 356,000) agreed well with the range determined from the crystallographic parameters (333,000 to 356,000); these values were slightly higher than those obtained from hydrodynamic data (313,000 to 333,000). The hexon crystallized into a bipyramidal-shaped crystal and the unit cell was cubic with $a = 149.9 \text{ \AA}$. The space group was $P2_13$ and there were 4 hexons/unit cell, 12 crystallographic asymmetric units/unit cell or 3 crystallographic units/hexon, each with a molecular wt of 110,000 to 119,000.

- 1913 CHARACTERIZATION OF CRYSTALS OF TYPE 5 ADENOVIRUS HEXON. (E.) Cornick, G. (Dept. Biophys., U. Chicago, Ill.), P. B. Sigler and H. S. Ginsberg. *J Molec Biol* 57(3):397-401, 1971.

Type 5 adenovirus hexon crystals were prepared by dialysis and mounted in thin-walled quartz capil-

laries containing stabilizing supernatant solution for X-ray diffraction; patterns were photographed and crystal densities were determined pycnometrically. The crystal structure was found to be isomorphous with type 2 and belonged to the cubic space group $P2_13$ with $a=b=c=149.9 \text{ \AA}$. In the asymmetric unit the calculated mass was $83,000 \pm 8000$ daltons and the volume fraction was 0.37 ± 0.03 . It is suggested that the asymmetric unit is 1/3 of the hexon.

- 1914 DEFECTIVE VIRIONS IN HUMAN ADENOVIRUS TYPE 12. (E.) Mak, S. (Dept. Biol., McMaster U., Hamilton, Ontario, Canada). *J Virol* 7(4):426-433, 1971.

Oncogenic human adenovirus type 12 and adenovirus type 2 were propagated in human cells in suspension, purified by cesium chloride equilibrium centrifugation and subsequently labeled with ¹⁴C-thymidine; the virus was added to a human epithelial cell line which was assayed for T-antigen and intranuclear inclusion body induction. Centrifugation in cesium chloride density gradients revealed 2 bands derived from adenovirus type 12 with a difference of 0.003 g/ml, indicating a difference in DNA content of 3-4%. A difference of 0.009 g/ml between the densities of type 2 and type 12 were observed, indicating a difference in DNA content of 8%. The number of virions added to give 37% survival (on the average one unit per cell) was about 150 to 300 for cell killing and about 3,000 to 10,000 for T-antigen induction; the lighter fractions had a much reduced specific infection compared to the virions of the heavy band of type 12, which showed a 7-10-fold higher specific infectivity. The T-antigen induction efficiency was similar within each virus preparation. Isopycnic centrifugation failed to reveal a significant generation of light virions in response to infection of cell with the heavy fractions after 2 passages in human cells. The oncogenicity of the defective virion is not known at present.

- 1915 PATHOLOGICAL RESPONSE OF THE CHICKEN EMBRYO TO AN AGENT WHICH CAUSES ACUTE LEUKOSIS (MAREK'S DISEASE). (E.) Evans, D. L. (M. D. Anderson Hosp. Tumor Inst., U. Texas, Houston), L. T. Patterson and J. N. Beasley. *Appl Microbiol* 21(2):321-326, 1971.

Detection of Marek's disease and the characteristics of the infecting agent were studied in the chicken embryo by means of microscopic techniques. Gross pathological appearance of small foci to gradually converging perilobular lesions with hepatomegaly, small granular-appearing white foci on the surface of the spleen with splenomegaly and liver discolorations, and thickenings of the chorioallantoic membrane with the appearance of small, white, granular clumps characterized the observed changes in the embryo. Microscopically, areas of focal necrosis occurred in the liver with no evidence of inflammatory reactions but with proliferation of lymphocytes and granulocytes in the liver and reticuloendothelial cell hyperplasia in the spleen. Changes occurred 3-4 days post-inoculation, and the agent was recovered from dander and feather follicles of 1-day-old infected chickens.

- 1916 SITE OF REPLICATION OF MAREK'S DISEASE VIRUS. (E.) Nazerian, K. (Reg. Poultry Res. Lab., East Lansing, Mich.). *Bibl Haemat* 36:210-212, 1970.

Two wk after inoculation of chickens with Marek's disease virus, virus particles were recovered from the feather follicles and from kidney cell cultures; birds had no gross lesions at the time of virus recovery. Higher virus yields were obtained from feather follicles than from kidney cells by the time that the chickens developed frank lesions. The virus particles which were recovered had the morphology of herpes virus, and 80% of the viruses had an outer envelope. Viruses were found in epithelial cells from feather follicles but not in epidermal cells, and they produced a cytopathic effect in cell cultures. Apparently, the feather follicle is the site of fully infectious Marek's disease virus in infected birds.

- 1917 HERPESVIRUS SAIMIRI INDUCED MALIGNANT LYMPHOMA: RECOVERY OF THE VIRAL AGENT FROM THE FATALY AFFECTED ANIMALS. (E.) Melendez, L. V. (Harvard Med. Sch., Southboro, Mass.), M. D. Daniel and R. D. Hunt. *Bibl Haemat* 36:751-753, 1970.

Three owl monkeys (*Aotus trivirgatus*) were inoculated i.m. with 3160 TCID₅₀ herpesvirus saimiri; 19-21 days thereafter the animals became moribund and were killed. Autopsy confirmed that the animals had died of reticulum cell malignant lymphoma. Herpesvirus saimiri was isolated from kidney tissues of these monkeys, and the 200 nm filtrate was inoculated i.m. into owl monkeys, causing the recipient monkeys to become moribund by day 17 postinoculation. Inoculation of 3 cotton-top marmoset monkeys (*Saguinus oedipus*) with herpesvirus saimiri produced similar results to those obtained in owl monkeys. Herpesvirus saimiri was isolated from kidney culture of 1 of the lymphomatous monkeys.

- 1918 HERPESVIRUS SAIMIRI: *IN VITRO* SENSITIVITY TO VIRUS-INDUCED INTERFERON AND TO POLYRIBOINOSINIC ACID:POLYRIBOCYTIDYLIC ACID. (E.) Barahona, H. H. (Harvard Med. Sch., Southboro, Mass.) and L. V. Melendez. *Proc Soc Exp Biol Med* 136(4): 1163-1167, 1971.

When owl monkey kidney cells were treated with Newcastle disease virus interferon prior to infection with herpesvirus saimiri, it was found that there was a delay of 24-48 hr in the onset of the cytopathic effect in cultures pretreated with interferon for 6 hr compared with virus-infected cultures not treated with interferon. The cytopathic effect was delayed by 6-7 days in cultures in which interferon was retained in the culture after virus infection. In both interferon-treated cultures, the cytopathic effect was reduced compared to control cultures. When polyriboninosinic acid:polyribocytidylic acid (poly I:C) was incubated with owl monkey kidney cells prior to infection, the herpesvirus saimiri cytopathic effect on the cultures was inhibited by 81%; at

concentrations of 10 µg/ml, poly I:C's protection of cells against viral damage was not constant. The protective efficacy of poly I:C was enhanced nearly 20% by the addition to the incubation medium of DEAE dextran in amounts of 50 µg/ml. When owl monkey cells were infected with herpesvirus saimiri and treated 1 hr postinfection with poly I:C and DEAE-dextran, no visible plaques appeared in the infected cultures, showing 100% inhibition of herpesvirus saimiri cytopathic effect.

- 1919 HERPESVIRUS SAIMIRI: III. PLAQUE FORMATION UNDER MULTI AGAR, METHYL CELLULOSE AND STARCH OVERLAYS. (E.) Daniel, M. D. (Harvard Med. Sch., Southboro, Mass.), H. Rabin, H. H. Barahona and L. V. Melendez. *Proc Soc Exp Biol Med* 136(4): 1192-1196, 1971.

Herpesvirus saimiri was inoculated into cultures of the following cell types for observation of plaque forming capacity: early and continuous passage owl monkey kidney cells, early passage marmoset kidney cells, early and continuous squirrel monkey kidney cells, continuous passage African green monkey kidney cells, and early passage fetal squirrel monkey heart, lung and intestine cells. Plaques developed under all experimental conditions in all cell types except African green monkey kidney cells and continuous squirrel monkey kidney cells; plaques in all cultures were of varying sizes. Squirrel monkey heart cells were the most susceptible to plaque induction by herpesvirus saimiri, being 4 times as susceptible as all the other cells. Harvests of single plaques produced heterogeneous plaques on serial plating. Plaques developed under all solidifying agents tested; the highest plaque counts were seen under methyl cellulose (mean plaque count of 60) while the mean plaque count with starch was 46. Protamine sulfate and, to a lesser extent, DEAE-dextran stimulated plaque production under agar, while arginine had no effect. The number of plaques was directly proportional to the virus dilution and to the volume of the virus inoculum.

- 1920 THE ASSOCIATION OF HERPES-LIKE VIRUS AND GUINEA PIG LEUKEMIA. (E.) Hsiung, G. D. (VA Hosp., West Haven, Conn.) and L. S. Kaplow. *Bibl Haemat* 36:578-583, 1970.

Herpes-like virus was isolated from minced kidney, liver, spleen and lung tissues of leukemic and non-leukemic strain 2 guinea pigs, a strain uniquely susceptible to an acute lymphoblastoid leukemia. Other guinea pig strains, including Hartley and Muta also harbored herpes-like virus. Herpes-like virus could not be isolated from supernates of tissue extracts, nor was it detected in electron microscopic examination of tissues taken directly from the strain 2 guinea pigs. Neutralizing antibodies to herpes virus were detected in all guinea pigs which harbored herpes-like virus, and in none of the guinea pigs examined which did not harbor herpes-like virus. C-type virus particles have also been observed in guinea pig

with leukemia, and it was thought that herpes-like viruses may act to complete the leukemogenic effect of C-type virus particles in leukemogenesis in strain 2 guinea pigs.

- 1921 THE INFLUENCE OF INHIBITORS OF MACROMOLECULAR SYNTHESIS ON CAPACITY OF HERPES SIMPLEX VIRUS TO INDUCE CHROMOSOMAL DAMAGE. (E.) Donner, L. (Czechoslovak Acad. Sci., Prague) and E. Gönzööl. *J Gen Virol* 10(3):243-250, 1971.

The effect of actinomycin D, puromycin and cytosine arabinoside on the capacity of herpes simplex virus isolated from human vesicular fluid of simple labial herpes maintained by passages on L cells was studied utilizing karyological analysis. The frequency of chromosomal aberrations in response to colchicine in control cells was 2% compared to 27-38% in infected cells with 2 types of lesions occurring in infected cultures as either chromosomal gaps and breaks or diffuse chromosomal lesions. When Actinomycin D was added either at the time of infection or 1 hr later, chromosomal damage did not result; when it was added 3 or 5 hr after infection, the frequency of chromosomal aberrations in infected cultures was not inhibited; similar results were obtained with treatment with puromycin. However, cytosine arabinoside treatment revealed 88-92% of metaphase in L cells having severe diffuse chromosomal lesions which appeared to be due to partial despiralization, erosion and/or extensive fragmentation of chromosomes, while control cells showed a relatively high incidence of metaphase plates with chromatid and isochromatid breaks but no diffuse chromosomal lesions. Results support the view that chromosomal changes induced by viruses are probably due to the action of early enzymes controlled by virus genes.

- 1922 RELATIONSHIP BETWEEN HERPES-TYPE VIRUS, CHINESE NASOPHARYNGEAL CARCINOMA AND AFRICAN LYMPHOMA. (E.) De-The, G. (Internat. Agency Res. Cancer, Lyon, France). *Bibl Haemat* 36:715-721, 1970.

Ultrastructural examination of cell cultures prepared from affected tissues of patients with nasopharyngeal carcinoma revealed the presence of herpes-type virus (HTV) capsids, nucleocapsids and extracellular virions, often attached to the cell surface. In addition, nasopharyngeal carcinoma cells were found to contain Epstein-Barr virus (EBV) type structural antigens and EBV related membrane reactive antigens. Eighty-four percent of nasopharyngeal carcinoma patients had high titers of EBV-type antibodies, while 10% of normals had EBV antibodies. The proportion of patients' sera having a high EBV antibody titer in nasopharyngeal cancer was similar to that in Burkitt's lymphoma. It appeared that HTV played some causal role in the EBV-associated development of nasopharyngeal carcinoma and Burkitt's lymphoma.

- 1923 STUDIES ON THE GROWTH OF HERPES SIMPLEX VIRUS IN LYMPHOBLASTOID CELLS. (E.) Floyd, R. (Baylor Coll. Med., Houston, Tex.), R. Glasser, V. Vonka and M. Benyesh-Melnick. *Acta Virol* 15(2):133-142, 1971.

Two Burkitt lymphoma cell lines, EB3 and P3J, were inoculated with herpes simplex virus; EB3 cells were infected at input multiplicities of 15 PFU/cell, and P3J cells were infected at input multiplicities of 10 PFU/cell. The first new virus was seen in P3J cells 15 hr after infection, and peak virus production ($6.5 \log_{10}$ TCID₅₀/ml) occurred at 25-30 hr. The number of viable cells in the infected P3J cells declined markedly and was too low for accurate measurement by 48 hr postinfection. Immunofluorescence staining of infected P3J cells with anti-herpes simplex virus antisera resulted in 80% of the cells showing antigen by 72 hr postinfection. Throughout the course of the experiment, about 2% of P3J cells contained Epstein-Barr virus. Herpes simplex virus replicated much less effectively in EB3 cells than in P3J cells; maximum titers ($4 \log_{10}$ TCID₅₀/ml) were not reached until 240 hr postinfection, and at no time did titers of virus increase appreciably from the initial titer. Viable cells in infected EB3 cultures did not decline markedly, as they did in P3J cultures. Immunofluorescence tests showed that few EB3 cells contained herpes simplex virus antigen. Epstein-Barr virus was found in EB3 cells, but herpes simplex virus did not cause an increase in Epstein-Barr virus titers in EB3 cells. Epstein-Barr virus was apparently not present in cells infected with herpes simplex.

- 1924 HERPESVIRUS TYPE 2 AND CERVICAL CARCINOMA. (E.) Melnick, J. L. (Baylor Coll. Med., Houston, Tex.) and W. E. Rawls. *Ann NY Acad Sci* 174(2): 993-998, 1970.

The presence of antibodies to herpesvirus type 2 was compared in women in various stages of cervical carcinoma in Houston. Eighty-two percent of women from lower socioeconomic levels with cervical carcinoma had antibodies to the virus, while only 22% without cervical abnormalities (controls) had antibodies; 9% of women from higher socioeconomic levels without abnormalities and 31% of those with cervical carcinoma had antibodies to herpesvirus type 2. Seventy-nine percent of women with cervical carcinoma whose lesions consisted of cells containing keratin and large extracellular pearl-like formations of keratin had viral antibodies. Eighty-seven percent of women with lesions with large-cell nonkeratinizing cells had viral antibodies. In women of the lower socioeconomic class, occurrence of antibodies associated with carcinoma *in situ* and cervical dysplasia was not significantly higher than in control women, 26% of cervical dysplasia cases and 38% of carcinoma *in situ* cases, resp., having virus antibodies. Although the cases and controls were not matched for sexual experience, a group of prostitutes was examined in which 54% of the members had antibodies to herpesvirus type 2. Incidence of virus antibody increased with age among women 20-50-yr-old, and declined thereafter.

- 1925 A HUMAN LEUKOCYTE CULTURE WITH AN UNUSUAL CYTOPLASMIC ENVELOPMENT OF HERPES-TYPE PARTICLES. (E.) Chandra, S. (John L. Smith Mem. Inst. Cancer Res., Pfizer Inc., Maywood, N. J.), W. Korol, R. P. Ames, D. P. A. Fabrizio and E. M. Jensen. *Cancer Res* 31(4):441-447, 1971.

Leukocyte cultures prepared from peripheral blood of a 33-yr-old X-ray technician who died of chronic myelogenous leukemia were observed by time-lapse cinematography and it was found that about 70% of the cells exhibited surface activity. The modal chromosome number in the blood cells was 45; there was monosomy in 1 chromosome in group C, and 1 lost G chromosome. The cytoplasm of infected G6 cells contained "naked" herpesvirus particles and virus particles enclosed in membranous sacs. Membranous sacs sometimes enclosed 2-3 particles. The sacs had a distinctive morphology, smooth on their outer surface and fringed on their inner surface. The enveloped herpes virus seen in the cytoplasm of the blood cells may have been a newly synthesized virion in the process of maturation or a reabsorbed virion in the process of degradation.

- 1926 EFFECTS OF CELL FUSION ON PRODUCTION OF THE MOUSE MAMMARY TUMOR VIRUS: IMMUNOFLOUORESCENCE STUDY. (E.) Lasfargues, E. Y. (Inst. Med. Res. Camden, N. J.), B. Kramarsky and D. H. Moore. *Proc Soc Exp Biol Med* 136(3):777-781, 1971.

Fusion of a cell line derived from a spontaneous mammary tumor in a (C57BL x Af) F₁ hybrid mouse with two normal mammary cells lines, MG4 and RMG was induced with Sendai virus; 10 days later the mixed cell cultures and their controls were independently injected s.c. into newborn Amsterdam/IMR rats. Cells containing 2-5 nuclei were readily observed 1 day after fusion and were easily distinguished from the associated MG4 or RMG cells. Within 48 hr about 20% of the cells in the mammary tumor line MG4 population were multinucleated, with 7% being recognized as true heterokaryons. In the mammary tumor line RMG combination a total of 35% were multinucleated cells, with the ratio of heterokaryons roughly 1:3. After 10 days of cultivation nuclear enlargement, multilobulation, nuclear pulverization and chromatin fragmentation were noted in both fused cell populations; these features were rare in the neoplastic cell line and absent in normal cell lines. In the neoplastic line, fluorescein-labeling revealed 10-25% positive cells over a 1-yr period; neoplastic-MG4 fused cells revealed 63, 75, and 84% positive cells in 3 separate experiments in contrast to fusion with RMG rat-mammary cells which gave a ratio of 15, 18, and 28% positive cells. These results were confirmed by whole-cell mount electron microscopy. The findings indicated a significant increase of mammary tumor virus production when neoplastic cells were fused with normal mammary cells from the same species.

- 1927 STUDIES ON ANTIGENIC CROSS-REACTIVITY OF ONCOGENIC RNA VIRUSES: CROSS-REACTIONS BETWEEN MOUSE MAMMARY TUMOR VIRUSES FROM DIFFERENT MOUSE STRAINS. (E.) Blair, P. B. (Cancer Res. Genet. Lab., U. California, Berkeley), D. W. Weiss and G. H. Smith. *Israel J Med Sci* 6(5):611-616, 1970.

Cross-reacting antigenicity between C3H/RIII and DBA strains of mammary tumor virus (MTV) and virus isolated from wild mice has been studied in infected mice from strains DBA, BALB/cfC3H, C3H and RIII. Test mice inoculated with either virus preparation combined with antisera against C3H, CeHf, or C3H/2 tissue did not develop mammary tumors within the test period compared to 3 of 12 females inoculated with RIII virus alone and 5 of 14 females inoculated with RIII virus combined with antiserum against virus-free BALB/c tissue which developed tumors. Antisera from rabbits immunized with the virus-free BALB/c, C57Bl, or I tissue extracts did not neutralize the biologic activity of mammary tumor virus, while antisera from those animals immunized with virus obtained from BALB/cfC3H, BALB/cfDBA, BALB/cfRIII or BALB/cfWILD mice either completely or partially inactivated the biologic activity of the various MTV with only 3 of the 15 test animals developing nodules. In view of the many similarities between mammary tumor virus and various other oncogenic RNA viruses, additional type-specific antigens may be present in the virion coat of the MTV.

- 1928 INTERFERENCE OF GROSS AND BITTNER VIRUSES. THE ANTAGONISM OF THEIR PATHOGENIC ACTION. (Sp.) De Asua, F. J. (Gallego Ctr. Buenos Aires, Argentina) and C. Abaurrea. *Sangre* 15(4):426-434, 1970.

The offspring of a strain of mice with a high incidence of leukemia development were foster-nursed by female mice of a strain having Bittner virus in their mammary milk. The latency period for leukemia development was increased in these foster-nursed mice, and the incidence rate for leukemia declined. Offspring of foster-nursed mice which were nursed by their natural mothers showed the same developments. Mice which developed leukemia in either generation did not develop mammary tumors and mice which developed mammary tumors did not develop leukemia. The reciprocal exclusion of mammary tumor and leukemia may have been due to interference between the pathogenic actions of Gross leukemia virus and Bittner virus, although both can exist together in the same animal. Mother mice dying of leukemia did transmit latent Bittner virus to their offspring, some of which developed mammary tumors, while mothers dying of mammary tumors could transmit leukemia to their offspring.

- 1929 NEUTRALIZATION OF MURINE MAMMARY TUMOUR VIRUS BY SERA OF WOMEN WITH BREAST CANCER. (E.) Charney, J. (Inst. Med. Res., Camden, N. J.) and D. H. Moore. *Nature* 229(5287):627-628, 1971.

Neutralization tests were carried out to determine whether murine mammary tumor virus (MTV) could be neutralized by serum prepared from breast cancer patients. In experiments with human serum, sera were used practically undiluted, and MTV was used in concentration of about 100 ID₅₀/0.1 ml. Inoculation of MTV treated with human breast cancer sera resulted in a mean incidence of MTV infection in C57BL mice of 69% compared to an 87% incidence of infection in mice inoculated with MTV treated with a control serum prepared

from normal human subjects. The presence of neutralizing antibodies in sera from human breast cancer patients and their absence from normal human sera indicated a viral etiology for the human disease.

80 COMPARATIVE PATHOLOGY AND ULTRASTRUCTURE OF RODENT SARCOMAS INDUCED BY THE MURINE SARCOMA VIRUS (MOLONEY). (E.) Perk. K. (Dept. Anim. Nat. Physiol., Hebrew U. Rehovot, Israel) and I. J. *J Comp Path* 81(2):173-178, 1971.

Swiss mice (BALB/c), rats and hamsters were given inoculations of murine sarcoma virus Moloney strain (SV-M), from the first passage to passages as advanced as number 96. In all groups, tumor incidence following virus inoculation was 100%; with successive serial passages a decreasing survival time in inoculated animals was always found. Sarcomas induced in mice by virus from early passage generations were composed primarily of large elongated cells with some port small fibrosarcoma cells and some mononuclear and cells. Tumors were rhabdomyosarcomas, with eosinophilic cytoplasm. Sarcomas induced by virus from later passage generations were composed of undifferentiated spindle cells; these tumors contained a great number of collagen fibers and showed infiltration by mononuclear round cells and leukocytes. These tumors were pleomorphic consisting of large undifferentiated spindle, round, or polygonal cells. Metastatic nodules in lungs were common. Occasionally typical Z bands were evident in tumor cells obtained from animals inoculated with early passage virus. Hamster tumors induced by early passage virus were characteristic spindle-cell sarcomas, and few multinucleated giant cells were also present. Tumors induced by virus passaged 5 times consisted only of round and irregularly shaped cells; multinucleated giant cells were not seen in these tumors. In general, mouse tumors were the most differentiated, and hamster tumors the least differentiated.

81 INFECTION OF MAMMALIAN UNFERTILIZED AND FERTILIZED OVA WITH ONCOGENIC VIRUSES. (E.) Baranska, W. (Wistar Inst. Anat. Biol., Philadelphia, Pa.), W. Sawicki and H. Koprowski. *Nature* 230(5296):591-592, 1971.

The effects of the Rh 911 strain of SV40 Moloney sarcoma virus and SV40 DNA on unfertilized and fertilized ova from 8-10 wk Swiss or C57B1/6 virgin mice were studied. The exposure of unfertilized ova to infection with the 2 viruses had little deleterious effect with some "fragmentation" occurring within 24 hours of cultivation *in vitro*. Similar results were obtained with fertilized ova and most of the ova, fertilized and unfertilized, yielded infectious virus.

82 THE AGE RELATED RESPONSES OF NEW ZEALAND MICE TO A MURINE SARCOMA VIRUS. (E.) Zdzar, A. F. (Natl. Cancer Inst., Natl. Inst. Health., Bethesda, Md.) W. Bietzel and N. Talal. *Int J Exp Immun* 8(3):501-509, 1971.

Murine sarcoma virus (Moloney) was injected s.c. and i.m. into mice of various ages of the following 8 strains: NZB, B/W, NIH Swiss, C57B1/6, C3H, AL/N, DBA/2 and BALB/c. All strains except C3H developed large tumors within 4-5 days after virus injection when virus was injected at 21 days of age or earlier; C3H mice developed smaller tumors than did the other strains, and had a longer latent period. In suckling and weanling mice, 100% of NZB and B/W mice and 93% of NIH Swiss mice had regressed tumors by day 12 postinoculation, while mice of the other 5 strains did not achieve 100% tumor regression until day 21 or later. NZB, B/W and NIH Swiss mice showed shorter periods elapsing between inoculation and the day on which 50% of inoculated mice survived than mice of other strains. An inverse relationship was found between regression time for tumors and age at inoculation; only 4 of 11 NZB mice inoculated at the age of 9 days survived, while 8 of 8 NZB mice inoculated at age 12 days survived. BALB/c mice developed the ability to regress tumors later than other strains. Six-wk-old NZB mice had lower mean tumor regression times than did 8- and 11-month-old mice of this strain.

1933 POTENTIATION OF MURINE SARCOMA VIRUS (HARVEY) (MOLONEY) ONCOGENICITY IN LACTIC DEHYDROGENASE-ELEVATING VIRUS-INFECTED MICE. (E.) Turner, W. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), P. S. Ebert, R. Bassin, G. Spahn and M. A. Chirigos. *Proc Soc Exp Biol Med* 136(4): 1314-1318, 1971.

Adult male BALB/c mice were inoculated with lactic dehydrogenase-elevating virus (LDV) prior to infection with Moloney or Harvey murine sarcoma viruses. LDV-infected mice challenged with Moloney virus developed regressing tumors in 49% fewer cases than Moloney virus-infected mice not previously infected with LDV (controls); LDV-infected mice had a survival time 61 days shorter than the survival time of controls and showed a 75% increase over controls in tumor incidence when challenged with Harvey virus with a complete absence of regressing tumors, compared to 100% tumor regression observed in controls. LDV-infected and Harvey-virus-challenged mice showed a 50% increase in mortality from virus-induced tumors over controls and a 22-day reduction in mean survival time. Inoculation of mice with a 10% extract of tumors from mice dually infected with LDV and Harvey virus produced a 10% tumor incidence in recipients, while LDV-infected mice inoculated with the same preparation showed a 60% incidence of tumor development.

1934 PHYSICAL ALTERATIONS OF A MURINE LEUKEMIA VIRUS COMPLEX IN MAMMALIAN CELL CULTURES. (E.) O'Connor, T. E. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and P. J. Fischinger. *Bibl Haemat* 36:250-256, 1970.

Cat cells were infected with feline leukemia virus (FeLV) and defective murine sarcoma virus; progeny

virus from infected cat cells was described as a FeLV pseudotype of murine sarcoma virus and was thought to consist of a defective murine sarcoma virus genome wrapped in a FeLV virus envelope. This modified murine sarcoma virus readily infected cat cells but not mouse cells; the infectivity of the modified virus for mouse cells could be restored by centrifuging the virus with excess murine sarcoma virus. Dog cell cultures could be infected with modified murine sarcoma virus, as could cultures of human embryonic lung cells. When cells from a cytogenetically abnormal (45 chromosomes) human fetus were infected with modified virus, it was found that the propagation of virus by infected cells decreased as the density of cell plating increased. Normal human embryonic muscle and skin cells and cells from a patient with Down's syndrome were all susceptible to infection with the modified murine sarcoma virus and all gave substantial yields of progeny virus. In all instances, the focus titration pattern of the virus was completely defective, but was normalized by the addition of FeLV during assay.

- 1935 ASPECTS OF THE HARVEY MURINE SARCOMA VIRUS COMPLEX (E.) Harvey, J. J. (Nat'l. Inst. Med. Res., London, England). *Bibl Haemat* 36:240-245, 1970.

A virus of the Harvey murine sarcoma virus family isolated by end-point dilution of Friend virus and designated small spleen virus (SSV) caused only slight splenomegaly in mice when injected alone and markedly reduced the immune response of mice to sheep erythrocytes. In adult BALB/c mice, SSV significantly accelerated erythroblastic splenomegaly caused by Harvey murine sarcoma virus. Sarcomas could not be induced in 3-wk-old BALB/c mice by injection of Harvey virus alone or after preinjection with SSV. However, injection of Harvey virus following SSV produced spleen wt increases more than twice as great as when Harvey virus alone was injected and more than 4 times as great as when SSV alone was injected. Mice given both viruses died within 3 wk with erythroblastic splenomegaly and cystic hemorrhagic lesions in the brain and lungs, while mice given either virus alone survived. SSV apparently enhances the effects of Harvey virus by means of a "helper" function in the Harvey murine sarcoma virus system. It was also reported that virus particles of an unusual "spoked" morphology were found in hamster sarcoma cells transformed by Harvey and Moloney murine sarcoma viruses.

- 1936 PROPERTIES OF A MURINE SARCOMA VIRUS. (E.) Kirsten, W. H. (Dept. Path., U. Chicago, Ill.), V. Schauf and J. McCoy. *Bibl Haemat* 36:246-249, 1970.

The comparative defectiveness of murine sarcoma virus Moloney strain (MSV-M) and murine sarcoma virus strain K (MSV-K) was investigated by observing early titers of these viruses in infected 3T3 mouse cells. The latter virus which was first recovered from high-titer pools of rat-adapted murine erythroblastosis virus was obtained in the present experiment from

mouse sarcomas, rat erythroblastosis virus and supernatants of murine sarcoma virus-transformed cells. Early (2 days postinfection) harvests of MSV-K virus derived from mouse sarcomas and rat erythroblastosis cultures yielded titration patterns which were independent of virus dilution in the cell cultures, while titers of virus from transformed mouse cells could be increased by the addition to the cultures of murine erythroblastosis virus. MSV-M virus titers could also be increased by addition of murine erythroblastosis virus, suggesting that this virus and MSV from transformed 3T3 cells were defective.

- 1937 TRANSFORMATION OF A CLONED RENAL EPITHELIAL CELL LINE BY MOLONEY MURINE SARCOMA VIRUS (M-MSV). (E.) Ikawa, Y. (Nat'l. Inst. Hlth., Tokyo, Japan), H. Yoshikura and H. Sugano. *Bibl Haemat* 36:312-322, 1970.

A clone of epithelial cells prepared from the kidney of mice and designated C3H2KB was infected with Moloney murine sarcoma virus (M-MSV) at varying dilutions and prepared for microscopic examination. Infected monolayers showed loose transformed foci consisting of refractile cells by day 4 postinfection. The number of foci was proportional to the titer of the M-MSV preparation used to infect the cells, showing a 1-hit dose response with 10^{-1} virus dilutions and a 2-hit dose response with 10^{-3} dilutions. Some foci were made up of small piles of spindle-cells and some were made up of small round cells; both types of cells in foci showed budding virus. M-MSV-transformed cells were implanted s.c. on the backs of male C3H/He mice; 12 of 20 mice receiving transplants developed local dorsal anaplastic medullary carcinomas which contained virus particles. When transformed cells were subcultured, they came to resemble normal C3H2KB cells after 8 subcultures.

- 1938 NEOPLASTIC BONE LESIONS INDUCED IN RATS AND HAMSTERS BY MOLONEY AND HARVEY MURINE SARCOMA VIRUSES. (E.) Soehner, R. L. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), S. Fujinaga and L. Dmochowski. *Bibl Haemat* 36:593-599, 1970.

Newborn rats and hamsters were inoculated i.p. with 0.2 ml of supernatants of homogenates of tumors induced by Harvey or Moloney strain murine sarcoma viruses. Both viruses induced bone tumors in rats; Moloney virus proved to be the more feasible experimental system, however, for Harvey virus usually killed rats before tumors had a chance to develop in the extremities. Moloney virus caused bone tumors in 1 of 9 injected rats with a 45 day latency; serially passaged virus caused incidences of bone tumors in rats ranging from 50-100%, with latencies ranging from 13-28 days. Harvey virus also caused bone tumors in hamsters; however, serial passage did not increase the tumor incidence among hamsters. Serial passage of Moloney virus-induced bone tumors increased the incidence of tumors in hamsters and shortened the latent period for tumor appearance.

-type virus particles were found in rat and hamster
one tumors induced by both Moloney and Harvey virus
strains.

939 EFFECT OF GROWTH ON THE GLYCOPROTEINS
FROM THE SURFACE OF CONTROL AND ROUS SAR-
COMA VIRUS TRANSFORMED HAMSTER CELLS. (E.) Buck,
A. (Div. Biol. Kansas St. U., Manhattan), M. C.
lick and L. Warren. *Biochemistry* 10(11):2176-2180,
1971.

aby hamster kidney cells in the plateau growth
phase and in the logarithmic growth phase were grown
in the presence of ^{14}C -labeled L-fucose-1 or L-fucose-2,
harvested, digested with pronase and subjected to gel
filtration tests. The material from rapidly growing
cells enriched with cell surface glycopeptides eluted
early from the column; material from slowly growing
cells had a comparatively small proportion of rapid-
ly migrating glycopeptides. The relative amounts of
early-eluting glycopeptides was also more abundant
for Rous sarcoma virus-transformed cells and de-
creased as the cells entered the slow plateau phase
of growth. However, material from virus-transformed
cells was more enriched with early-eluting glycopep-
tides than was material from untransformed cells.

940 THE RNA OF RNA-CONTAINING TUMOR VIRUSES.
(E.) Bader, J. P. (Natl. Cancer Inst.,
Natl. Inst. Hlth., Bethesda, Md.). *Bibl Haemat*
5:140-143, 1970.

the interval between completion of synthesis of viral
RNA by Rous-associated virus and Rauscher murine
leukemia virus was investigated by exposing infected
cells to ^3H -uridine and collecting fluids at 10 or
5 min intervals. Radioactive virion RNA was first
detected 80 min after the addition of labeled uridine,
indicating that the minimum interval between com-
pletion of viral RNA synthesis and its incorporation
into virions is about 70-75 min. RNA produced by
these viruses was found to be conventional viral RNA;
no labeled cellular RNA was found. When actinomycin
(2 $\mu\text{g}/\text{ml}$) was added to cultures of virus-infected
cells within 15 min after the addition of ^3H -uridine
to the cultures, the appearance of labeled RNA was
prevented; addition of actinomycin D 30 min after
uridine did not affect the appearance of labeled RNA.
Cycloheximide (10 $\mu\text{g}/\text{ml}$) addition resulted in inhibi-
tion similar to that produced by actinomycin D.

941 DEOXYRIBONUCLEIC ACID POLYMERASES OF ROUS
SARCOMA VIRUS: KINETICS OF DEOXYRIBONUCLEIC
ACID SYNTHESIS AND SPECIFICITY OF THE PRODUCTS. (E.)
Garapin, A. C. (Dept. Microbiol., U. California, San
Francisco), L. Fanshler, J. A. Leong, J. Jackson, W.
Levinson and J. M. Bishop. *J Virol* 7(2):227-232, 1971.

the interrelationship between the synthesis of single-
stranded DNA in association with the RNA genome of
the virus and the synthesis of double-stranded DNA
by an enzyme capable of utilizing double-stranded DNA
as a template has been studied in Rous sarcoma virus

by analyzing the kinetics of DNA synthesis at limiting
substrate concentrations. At very low substrate con-
centrations (thymidine triphosphate was limited) the
initial enzymatic product was single-stranded DNA,
both free and complexed to viral RNA, and after an
appreciable time the final double-stranded DNA was
detected. At higher concentrations the final double-
stranded DNA was detected much earlier in the reaction.
Both products contained nucleotide sequences which
were complementary to regions in the 70S viral RNA;
with hybridization only a small amount of DNA annealed
to any given RNA molecule to give hybrids having a
buoyant density virtually identical to that of single-
stranded RNA. The results suggest that segments of
the 70S viral RNA are transcribed into single-stranded
DNA followed by synthesis of double-stranded DNA which
utilizes the primary enzymatic product as template in
a manner not yet determined.

1942 NUCLEOTIDE COMPOSITION OF RNA HYBRIDIZED
TO HOMOLOGOUS DNA FROM CELLS TRANSFORMED
BY AVIAN TUMOUR VIRUSES. (E.) Baluda, M. A. (UCLA
Sch. Med., Los Angeles, Calif.) and P. D. Markham.
Nature 231(20):90-91, 1971.

The average base composition of the RNA which was
hybridized to homologous DNA from chick embryo fibro-
blasts transformed by Schmidt-Ruppin Rous sarcoma
virus (SR-RSV) or avian myeloblastosis virus (AMV)
was compared with the base composition of the input
viral RNA. The use of fragmented viral RNA and a
modified washing procedure which excluded the use
of ribonuclease assured the recovery of all the ribo-
nucleotides which had been hybridized and the absence
of partially hybridized ribonucleotide sequences.
The base compositions of hybridized ^{32}P -RNA and of
input ^{32}P -SR-RSV-RNA were identical; similar results
were found for ^{32}P -AMV-RNA. These results provide
further evidence for a DNA intermediate in the re-
plication of RNA tumor viruses.

1943 DEOXYRIBONUCLEIC ACID POLYMERASE ASSO-
CIATED WITH AVIAN TUMOR VIRUSES: SECON-
DARY STRUCTURE OF THE DEOXYRIBONUCLEIC ACID PROD-
UCT. (E.) Fanshler, L. (Dept. Microbiol., U.
California, San Francisco), A. C. Garapin,
J. McDonnell, A. Faras, W. Levinson and J. M.
Bishop. *J Virol* 7(1):77-86, 1971.

The major product of DNA synthesis by the Rous
sarcoma virus-associated polymerase was a DNA:RNA
hybrid which co-sedimented with 70S viral RNA and
had the same buoyant density as that of single-
stranded RNA. This 70S DNA:RNA eluted from hydrox-
yapatite in a manner similar to that of isolated
70S viral RNA. Treatment of the 70S complex with
ribonuclease in 0.3 M NaCl gave a 4S DNA:RNA hybrid
with approximately equimolar DNA and RNA contents
and which eluted from hydroxyapatite similarly to
single-stranded RNA. The late product contained
DNA which was not associated with RNA; analysis
by hydroxyapatite chromatography indicated that
the late product had little single-stranded DNA
but seemed to consist of double-stranded DNA. By

12 hr after initiation of enzymatic synthesis, no hybrid molecules were detectable in the product, which consisted primarily of double-stranded DNA.

- 1944 INHIBITION OF GROWTH OF UNINFECTED AND ROUS SARCOMA VIRUS-INFECTED CHICK-EMBRYO FIBROBLASTS BY RIFAMPICIN. (E.) Robinson, H. L. (Stanford U. Sch. Med., Calif.) and W. S. Robinson. *J Nat Cancer Inst* 46(4):785-788, 1971.

The effect of rifampicin on the growth of uninfected and Rous sarcoma virus-infected chick embryo fibroblasts was studied in 10-day chick embryo cultures by means of virus infectivity assay and cell counting techniques. Cells not treated with rifampicin proliferated with a doubling time of around 20 hrs whereas concentrations as low as 20 µg/ml inhibited the growth of both normal and transformed cells, the degree of inhibition correlating with the concentration of the drug and the length of time of exposure. The agent had little or no effect on virus production by cultures grown in the presence of the drug for 24 or 48 hrs but at 72 and 96 hrs the amount of virus produced was markedly decreased in response to 60 µg/ml of the agent. These results suggest that the inhibition of focus formation may be due to inhibition of cell growth rather than to a specific effect of the drug on cell transformation.

- 1945 LACK OF CORRELATION BETWEEN CONVERSION BY RNA TUMOUR VIRUSES AND INCREASED AGGLUTINABILITY OF CELLS BY CONCANAVALIN A AND WHEAT GERM AGGLUTININ. (E.) Moore, E. G. (McArdle Lab. Cancer Res., U. Wisconsin, Madison) and H. M. Temin. *Nature* 231(5298):117-118, 1971.

Agglutination studies with wheat germ agglutinin and concanavalin A of parallel uninfected, and Rous sarcoma virus (RSV)-and avian leukosis virus (RAV)-infected chicken cells, and parallel uninfected and murine sarcoma virus (MSV)-and murine leukemia virus (MLV)-infected rat and mouse cells, all in secondary or tertiary cultures, were performed. A serological scale of 0 to +++, based primarily on the cell aggregate size was used to estimate the degree of agglutination, and the specificity of the agglutinin cell interaction was demonstrated. In agreement with earlier findings, normal cells showed negligible or very low agglutinability. Significant increases were found after trypsin treatment. With the exception of B77-virus-converted rat cells, cells converted by these RNA tumor viruses (Schmidt-Ruppin virus, B77 virus, P-RSV, MSV) did not show marked increases in agglutinability. Rat cells converted by B77 virus, however, displayed markedly increased agglutinability. Control experiments were able to confirm the increased agglutinability of mouse cells transformed by DNA tumor viruses. These results demonstrate that changes in response to wheat germ agglutinin and concanavalin A are not necessary concomitants of neoplastic transformation in cell culture.

- 1946 ULTRAVIOLET SPECTROGRAMMIC MICROSCOPE STUDIES OF ROUS SARCOMA VIRUS CULTURED IN CELL-FREE MEDIUM. (E.) Alexander-Jackson, E. (U. San Diego, Calif.). *Ann NY Acad Sci* 174(2):765-781, 1970.

Partially purified Rous sarcoma virus was filtered into cell-free broth and examined under the UV spectrographic microscope. After 8 hr of incubation in the broth, spectrograms revealed marked molecular activity, including an increase in DNA; DNA had decreased by 16 hr of incubation. Under the electron microscope, virus-containing filtrates showed the presence of small zooglycal symplasm L forms, and a few small coccid bodies. Pleomorphic L forms similar to mycoplasma and some slender filaments were seen after 8 hr in culture. By 16 hr, many acid-fast and nonacid-fast bodies were seen. Filtered growth broth streaked on agar did not grow although unfiltered broth which contained virus did show growth on agar; the growth resembled the bacterial isolates sometimes seen in association with Rous sarcoma virus infection.

- 1947 A DEFECTIVE ROUS SARCOMA VIRUS: THE D-5 STRAIN. (Rus.) Kuznetsov, O. K. (N. N. Petrov Res. Inst. Oncol., Leningrad, U.S.S.R.) and A. M. Dyad'kova. *Vop Onkol* 17(1):35-41, 1971.

The D-5 strain of the Rous sarcoma virus (RSV) isolated from chicken tumor cells and purified of its contaminant Rous leukosis virus (CRV₅) was capable of inducing transformation foci in normal chicken embryo cell cultures. The transformed cells constituted 3 categories: non-virus producing, low yield virus-producing or high yield virus-producing cells. Superinfection of these transformed cell cultures with avian leukosis virus, RAV-1, or with the CRV₅ strain led to the production of RSV particles by former non-virus producing cells and increased the yield in RSV particles in low-yield virus-producing cells. The D-5 strain was thus considered to be a defective strain and named D-5(0); the leukosis viruses (including the CRV₅) were considered to be helper viruses because of their capacity to activate the reproduction of the D-5(0) virus. The defective virus exhibited no interference with the avian leukosis viruses of subgroups A or B and gave no cross-reactions of neutralization with viruses of subgroups A, B or C. When contaminated with the CRV₅-strain of subgroup A, the virus exhibited features of an RSV of subgroup A in the interference and neutralization reactions. The D-5(0) virus could not be classified under any of the subgroups A, B or C by its immunological behavior in the absence of its contaminant.

- 1948 CHANGES AT THE MEMBRANES OF LEUKOSIS VIRUS TRANSFORMED CELLS AND VIRUS AS DETECTED BY ELECTRONMICROSCOPY. (E.) Morgan, H. R. (U. Rochester Sch. Med. Dent., N. Y.). *Bibl Haemat* 36:144-147, 1970.

nicked embryo fibroblasts were infected with Fujinami strain Rous sarcoma virus and treated with hyaluronidase (300 National Formulary U) in order to remove the layer of acid mucopolysaccharide covering the surface of infected cells. Under the electron microscope, large masses of virus particles could be seen on the surfaces of infected cells not treated with hyaluronidase, and the masses were covered with a layer of acid mucopolysaccharide. Some virus particles incorporated the acid mucopolysaccharide lay into the viral envelope as they budded from transformed cells. No virus particles were seen in cultures treated with hyaluronidase, suggesting that the enzyme had released the viral aggregates from the cell surface.

49 FAILURE TO DETECT HOMOLOGY BETWEEN THE DNA OF THE SHOPE FIBROMA VIRUS AND THE DNA OF A HYPERSENSITIVE CELL. (E.) Jacquemont, B. (Natl. Inst. Med. Res., Lyon, France), M. H. Richard and J. Grange. *J Gen Virol* 10(3):237-242, 1971.

The structural homology between the DNA of Shope fibroma virus and that of RK 13 cells of a DNA-DNA hybridization were studied in infected RK 13 cell cultures and tumors of adult rabbits by thymidine labeling. Shope fibroma virus DNA hybridized more than 70% with its homologue; the percentage hybridization obtained with the DNA of RK 13 cells of calf thymus and *E. coli* were similar to those obtained with the background. A constant quantity of labeled DNA from RK 13 cells showed hybridization with its homologue (30%), with calf thymus DNA (6.4%), with DNA from *E. coli* (2.2%) and with Shope fibroma virus DNA (1.2%). Absence of hybridization between the Shope fibroma virus DNA and DNA of the rabbit cell could mean that there is a difference between the mechanism of induction of tumors of Shope fibroma virus and other oncogenic viruses.

50 TRANSFER RNA METHYLASES OF NORMAL CELLS, VIRUS-TRANSFORMED CELLS AND TUMORS DERIVED FROM TRANSFORMED CELLS. (E.) Fujioka, S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), R. C. Ting and R. C. Gallo. *Cancer Res* 31(4):1445-1456, 1971.

tRNA methylase (tRNA methylase) was assayed in normal Swiss or C3H mouse embryo cells, normal rat kidney cells, rat kidney cells transformed by SV40, polyoma virus or murine sarcoma virus Moloney, and in tumors obtained by inoculating rats with murine sarcoma virus-transformed cells. No differences were observed between tRNA methylase specific activity or capacity in normal cells and murine sarcoma virus-transformed cells; the tRNA methylase capacity of normal cells and of transformed cells was 59.1 and 59.0 pmoles of S-adenosyl-methionine/ μ g of tRNA, resp. Specific tRNA methylase activities in normal and murine sarcoma virus-transformed cells were 24.0 and 26.2 pmoles of S-adenosyl-methionine/25 μ g of tRNA, resp. Both specific activity and capacity were increased 2-6-fold in tumors induced by murine sarcoma virus-transformed

cells over specific activity and capacity in normal tissues. SV40 and polyoma virus-transformed cells contain higher tRNA methylase activities and capacities than nontransformed normal cells. tRNA methylase capacity in normal and polyoma virus-transformed cells was 33.8 and 53.2 pmoles of S-adenosyl-methionine/ μ g of tRNA, resp.; tRNA specific activity in normal and SV40-transformed cells was 16.3 and 36.9 pmoles of S-adenosyl-methionine/25 μ g of tRNA, resp.

1951 INFECTIVITY OF MOLECULAR FORMS OF SIMIAN VIRUS 40 DNA. (E.) Trkula, D. (Baylor Coll. Med., Houston, Tex.), S. Kit, T. Kurimura and K. Nakajima. *J Gen Virol* 10(3):221-229, 1971.

The infectivities of superhelical simian virus 40 (SV40) DNA extracted from African green monkey kidney cells with the products formed when purified SV40 DNA was adsorbed to replicate monolayer cultures of African green monkey kidney cells, transformed human skin and primary mouse kidney cells for various periods of time was studied by means of thymidine labeling techniques. Approximately 23-48% of the input viral 3 H-DNA was adsorbed to African green monkey kidney cells, human skin cells and mouse kidney cells in 2 hr. Approximately 1/3 of the denser Form I DNA was converted to less dense, nicked DNA during the 2 hr adsorption period to African green monkey kidney cells, 40% with transformed human skin cells and about 25% with mouse kidney cells. Specific infectivities of DNA extracted from the cultures were of the same magnitude as that of input DNA in the 3 types despite the fact that as much as 69% of the extracted DNA represented nicked molecular forms. At 37-39 hr after infection, about 76% of the radioactivity was recovered in the heavy DNA peak and about 21% in the light DNA peak from SV40-infected African green monkey kidney cells, with the heavy fractions showing a sedimentation coefficient of about 21S (Form I DNA) and 16-18S; the latter showed 25% of the specific infectivity of Form I DNA.

1952 RELATIONSHIP BETWEEN VIRUS-INDUCED CELLULAR DEOXYRIBONUCLEIC ACID SYNTHESIS AND TRANSFORMATION BY SIMIAN VIRUS 40. (E.) Fox, T. O. (Dept. Biochem., Princeton U., N. J.) and A. J. Levine. *J Virol* 7(4):473-477, 1971.

Monolayer cultures of 3T3 mouse cells labeled with 32 P were infected with simian virus 40 (SV40); 2 hr later 3 H-thymidine was added and at 24 hr and 48 hr after infection the infected cells were sedimented through a Ficoll gradient. Transformation frequencies of cells obtained 24 hr after infection with a fast sedimenting peak (in the S period) were 40-57% compared to 7-12% for cells with a slow sedimenting peak (in the G-1 period). After 48 hr the fast sedimenting peak gave transformation values of 9-26% compared to 8-32% for the slow sedimenting peak, resulting in ratios of fast sedimenting transformation to slow sedimenting transformation that were considerably lower for the 48 hr sample than for the 24 hr sample. These results indicated that cellular DNA synthesis during the first 24 hr after infection of 3T3 cells is necessary for efficient transformation.

- 1953 STRUCTURAL PROTEINS OF SIMIAN VIRUS 40.
(E.) Barban, S. (Natl. Inst. Allerg.
Infect. Dis., Natl. Inst. Hlth., Bethesda, Md.)
and R. S. Goor. *J Virol* 7(2):198-203, 1971.

The characteristics of structural proteins of simian virus 40 (SV40) in infected African green monkey kidney cells and Vero cells were analyzed by polyacrylamide gel electrophoresis and isoelectric focusing procedures. Staining patterns showed 2 major bands and 3-4 minor bands; virions labeled with ^3H - or ^{14}C -amino acids gave relative proportions of radioactivity of 80% for peaks I and II, 7% for peak III, 7-9% for peak IV and 4% for a slowly migrating band at the top of the gel with estimated molecular weights of approximately 45,000 (I, II), 29,000 (III), and 16,000 (IV) daltons. The fastest sedimenting peak (I) with 35-40S value was identified as the nucleocapsid-DNA complex; the second major peak (II) had an S value between 2.5-5.0 and was associated with the viral capsid protein, which was separated into 2 components with isoelectric optima of pH 6.4 and 5.5. Immunological analysis of peaks I and II revealed 2 distinct precipitin lines with rabbit antiserum prepared against highly purified dissociated SV40 particles. The location of the peak III peptide in the architecture of the virion is not known.

- 1954 HOMOLOGY BETWEEN SV40 DNA AND DNA OF NORMAL AND SV40-TRANSFORMED CHINESE HAMSTER CELLS.
(E.) Hirai, K. (Wistar Inst. Anat. Biol., Philadelphia, Pa.) and V. Defendi. *Biochem Biophys Res Commun* 42(4): 714-722, 1971.

The extent of the homology between simian virus 40 (SV40) DNA and the DNA of normal and virus-transformed Chinese hamster cell has been studied by DNA-RNA hybridization techniques. The size of the complementary RNA (cRNA) synthesized *in vitro* by *E. Coli* DNA-dependent polymerase was rather heterogeneous, with a peak of 10S and a broad distribution above and below this value. The thermal stability of DNA-RNA complexes indicated that long RNA molecules from both cell lines were involved. The heat stability of SV40 DNA + cell DNA hybrids was different from that of ^3H -SV40 DNA + SV40 DNA hybrids and from ^3H -cell DNA + cell DNA hybrids. Results indicated that normal Chinese hamster DNA as well as SV40-transformed cells do contain some homologous nucleotide sequence comparable to SV-40 DNA.

- 1955 ELECTRON MICROSCOPIC DETECTION OF TRANSFORMING VIRUSES INDUCED BY CELL ASSOCIATION: I. THE SV40 MODEL. (E.) Menezes, J. (Fac. Med. U. Ottawa, Ontario, Canada). *Int J Cancer* 7(2):331-338, 1971.

SV40-transformed cells were co-cultivated or fused with permissive or insusceptible cells from monkey, bovine, porcine or hamster cell cultures; cell fusion was accomplished by mixing, centrifuging and

cultivating the 2 cell types to be fused in the presence of UV-inactivated Sendai virus. Fusion and co-cultivation products were examined under the electron microscope to detect SV40 particles, and detection of virus by electron microscopy was compared with detection of virus by infectivity tests. An average of approximately 2 SV40-infected cells containing virus particles were needed for a positive detection of SV40 particles by microscopy, whereas infectivity tests yielded positive results using fewer cells. The minimum time required to detect SV40 in cell cultures after infection, co-cultivation or fusion was about 1-2 hr less using electron microscopy than it was using infectivity tests. Naturally insusceptible cells could be successfully used for the induction of a virus by fusing these cells with transformed cells.

- 1956 STUDIES ON THE HAMSTER PAPILLOMA AND THE HAMSTER VIRUS LYMPHOMA. (E.) Graffi, A. (German Acad. Sci., Berlin), E. Bender, T. Schramm, I. Graffi and D. Bierwolf. *Bibl Haemat* 36:293-303, 1970.

Papova virus was found in papillomas arising from the hair follicles of young hamsters; although the tumors were readily transplantable, no viruses were found in transplanted papillomas. S.C. inoculation of cell-free virus filtrate from the papillomas into newborn hamsters yielded 5-10% tumor incidence; inoculation with skin tumor preparations also produced a 30-80% incidence of leukemia and lymphoma with latencies of 4-8 wk. Lymphomas often affected the thymus, kidneys and liver. Papova virus DNA whether administered with or without RNase produced high incidences of lymphomas. Antipapova virus antiserum prepared in rabbits counteracted the oncogenic effects of the virus; only 3 of 64 hamsters injected with a virus concentration of 1:10 and immunized with anti-papova virus antiserum developed lymphomas.

- 1957 GLYCOPEPTIDES FROM THE SURFACE OF CONTROL AND VIRUS-TRANSFORMED CELLS. (E.) Buck, C. A. (Div. Biol., Kansas St. U., Manhattan), M. C. Glick and L. Warren. *Science* 172(3979):169-171, 1971

Normal and polyoma virus-transformed hamster cells, normal and murine sarcoma virus-transformed BALB/3T3 mouse cells, and normal and Rous sarcoma virus-transformed chick embryo cells were digested in trypsin to remove glycopeptides. Glycopeptides from normal and transformed cells were digested exhaustively with pronase and prepared for gel filtration (Sephadex G-50). In every case, elution patterns on gel filtration showed glycopeptides from transformed cells eluting 5-10 fraction numbers ahead of glycopeptides from normal cells. Results were similar for all cell of whatever origin, transformed by all the various viruses.

- 1958 GLYCOSYLTRANSFERASE ACTIVITIES IN NORMAL AND POLYOMA-TRANSFORMED BHK CELLS. (E.) Den, H. (Dept. Biol., Johns Hopkins U., Baltimore,

d.), A. M. Schultz, M. Basu and S. Roseman. *J Biol Chem* 246(8):2721-2723, 1971.

Normal and polyoma virus-transformed baby hamster kidney fibroblasts showed differing levels of sialyltransferase activity. The activity of the sialyltransferase catalyzing the formation of hematoside from lactosylceramide and cytidine monophospho-N-acetylneuraminic acid was reduced to about 15% of normal cell levels in virus-transformed cells. Sialyltransferase activity in homogenates from normal cells was markedly increased (about 6-fold) when certain phospholipids were added to the incubation mixtures; phospholipids exhibiting the greatest stimulatory effect were phosphatidylglycerol and cardiolipin. In virus-transformed cells, galactosyltransferase was reduced to 36-49% of normal cell levels, and glucosaminyltransferase was reduced to 87% of normal cell values. Phosphatidylglycerol and cardiolipin had no effect on sialyltransferase in virus-transformed cells that was comparable to their effect on normal cells.

59 FURTHER MANIFESTATIONS OF ABORTIVE TRANSFORMATION OF BHK 21 CELLS BY POLYOMA VIRUS. (E.) Taylor-Papadimitriou, J. (Emp. Cancer Res. Fund Lab., London, England), G. P. Stoker and P. Riddle. *Int J Cancer* (2):269-276, 1971.

The effect of polyoma virus on resting baby hamster kidney 21 cells in serum-deprived cell cultures was studied by means of autoradiography and time-lapse cinematography. Over 50% of the cells were stimulated by virus to incorporate ³H-thymidine over a 48 hr period in the absence of serum; the addition of serum did not markedly affect the percentage of cells stimulated. In contrast, control extracts of mouse embryo cells showed a serum concentration-related response. Approximately 21-60% of the cells infected with partially purified virus incorporated ³H-thymidine, while those exposed to empty capsids did not. Viral-stimulated DNA synthesis first appeared after about 30 hr. Disorientation of infected cells was first detectable after 25-30 hr and was maximal 2-3 days after infection as determined by time-lapse cinematography. It now seems likely that different cells have different requirements for the factors in serum which are required for growth and integrity.

60 TRANSPORT INHIBITORS RELEASED BY 3T3 MOUSE CELLS AND THEIR RELATION TO GROWTH CONTROL. (E.) Pariser, R. J. (Med. Coll. Virginia, Richmond) and D. D. Cunningham. *J Cell Biol* 49(2):525-529, 1971.

Transport of uridine-³H and phosphate-³²P into the acid-soluble fraction of 2 lines of mycoplasma-free confluent cells (3T3 and polyoma-transformed Py3T3) was assayed 20 min after the initiation of cell division by the addition of 10% serum medium. When 3-altered medium with 10% fresh serum was added to confluent cultures, only 65% and 33% transport-

stimulating activity was observed, resp., for phosphate and uridine compared to 100% activity for fresh medium with 10% serum; 3T3-altered, dialyzed medium showed 48% and 60% activities, resp., while 3T3-altered, dialyzed medium with 10% fresh serum showed 90% and 108% activities, resp. The increase in activity of exhaustively dialyzed 3T3-altered medium from which a free inhibitor was presumably lost suggested that the serum possessed transport-stimulating activity other than that due to the simple binding of inhibitor. Subconfluent 3T3 cells were fully able to reduce the transport-stimulating activity of fresh medium at a rate roughly equal to that for confluent 3T3 cells. Noncontact-inhibited (subconfluent and Py3T3) cells released an inhibitor for uridine transport only, and they inactivated stimulatory factors for both uridine and phosphate transport present in fresh 10% serum medium.

1961 TESTS FOR ONCOGENICITY OF VIRUSES UNDER CONDITIONS OF ALTERED HOST AND VIRUS. (E.) Larson, V. M. (Merck Inst. Ther. Res., West Point, Pa.), P. A. Conrad, W. R. Clark and M. R. Hilleman. *Proc Soc Exp Biol Med* 136(4):1304-1313, 1971.

Hamsters were thymectomized at birth and at various times thereafter were inoculated s.c. with viruses of various strains in various multiplicities. Thymectomized hamsters given polyoma virus at 7 days of age developed tumors in 83% of cases, while thymectomized hamsters given polyoma virus at 4 months of age developed tumors in 28% of cases; nonthymectomized hamsters inoculated at 7 days of age developed tumors in 37% of cases and in 7% of cases inoculated at 4 months of age. Tumorigenesis by SV40 was similarly enhanced by thymectomy; 80% of the thymectomized animals and 42% of the sham-operated animals developed tumors. Tumor induction by adenovirus 7 was enhanced by thymectomy (70% of thymectomized and 12% of unthymectomized animals developed tumors), and tumor induction by adenovirus 3 was moderately enhanced by thymectomy. Thymectomized hamsters were also inoculated with influenza virus, poliovirus, ECHO virus, reovirus, vaccinia virus or *Mycoplasma orale*; tumor induction with these agents was rare in both thymectomized and unthymectomized animals. Hamsters given inoculations of adenovirus when newborn, 1-, 3-, or 12.5-14-month-old developed tumors in the newborn group only; however, SV40 induced tumors in animals of all ages. While the tumorigenicity of the viruses depended on the amount of virus inoculated, virus strain and passage level did not appreciably affect the tumorigenicity of the virus used.

1962 TRANSFER RNA METHYLASE ALTERATIONS IN POLYOMA TRANSFORMED RAT EMBRYO CULTURE CELLS (E.) Gallagher, R. E. (Natl. Inst. Hlth., Bethesda, Md.), R. C. Y. Ting and R. C. Gallo. *Proc Soc Exp Biol Med* 136(3):819-823, 1971.

Cells from 12-day-old embryos of inbred BN rats transformed with polyoma virus SE3049 were injected into

adult BN rats; cultures of the resulting tumor were treated with *E. coli* tRNA (30µg) or yeast tRNA (60µg) prior to ¹⁴C- methyl group incorporation determinations. With *E. coli* tRNA as methyl acceptor and with excess amounts of enzymes, label incorporation showed a 3-6-fold difference in rate of reaction, and a 7-fold increment in the extent of methylation was noted in the tumor cell system. With yeast tRNA, methylation was almost undetectable in the nontransformed control cells but reached an extent of approximately 0.7 µmoles/mg of tRNA with the tumor preparation. Uridine-labeled tRNA after 90 min incubation accounted for 92% of the acid precipitable counts in the control system, compared to 61% in the tumor system; the presence of ammonium ions did not affect the rate of reaction. The marked differences in capacity to methylate heterologous tRNA substrates suggests that qualitative differences may exist between the methylases of paired cell lines.

1963 VIRAL SENSITIVITY OF CELLS DERIVED FROM NORMAL OR PATHOLOGICAL RABBIT TISSUE. (F) Chardonnet, Y. (Fac. Med. Lyon, France) and L. Barrilliot. *Path Biol* 19(1-2):65-75, 1971.

1964 IMMUNOLOGIC REACTIVITY TO VIRAL ANTIGENS IN CHICKENS INFECTED WITH AVIAN LEUKOSIS VIRUSES. (E.) Meyers, P. (Dept. Microbiol., U. Miami, Fla.) and R. M. Dougherty. *J Nat Cancer Inst* 46(4): 701-711, 1971.

The effect of congenitally transmitted avian leukosis virus on the immunologic responsiveness of chickens to related and unrelated viruses was studied utilizing chick-embryo fibroblast tissue cultures by means of hemagglutination-inhibition testing. All congenitally infected birds at ages 2½, 6 and 25 wk retained their viremia for the entire 8 wk of the experimental period and failed to produce antiviral neutralizing antibody with the exception of one bird in the 2½-wk-old group, which developed a low but significant level of antibodies by 8 wk which coexisted with the viremia. In the control group, the youngest age groups had uniform responses in terms of viremia, and antibody production with viremia became apparent by wk 1 and persisted until wk 5. Antibodies to RAV-1 strain of avian leukosis virus first appeared in these groups at 2 wk with higher titers noted at 8 wk. In contrast, viremia and antibody developed in a smaller proportion of the 23-wk-old chickens, the viremia was of shorter duration and ultimate antibody titer was lower. When challenged with heterologous influenza virus A, control and congenitally infected birds in all age groups responded with high titers of antibody, with the congenitally infected 2½-wk-old group showing lower titers by one-half than the appropriate control group. Response to AV-6 Harris strain of avian leukosis virus was similar in 25-wk-old birds of both control and congenitally infected groups, whereas in 6-wk-old birds 18 of 19 control as compared to 6 of 17 congenitally infected birds developed antibodies to the virus. Age-dependent inhibition of RAV-6 antibody response in congenitally infected birds cannot at this time be explained.

1965 EXTRACTABLE HERPESVIRUS ANTIGENS FROM CHICKENS WITH MAREK'S DISEASE. (E.) Ahmed, M. John L. Smith Mem. Cancer Res., Pfizer Inc., Maywood, N.J.), J. B. Leech, S. M. Slattery and G. Schidlovsky. *Int J Cancer* 7(2): 339-345, 1971.

Feather follicles from chickens infected with Marek's disease herpesvirus (MDHV) were prepared by centrifugation and sonication for immunofluorescence and microimmunodiffusion tests. Both tests demonstrated MDHV antigens in epithelial cells from follicular tissue. Positive antigen reactions were also obtained from chickens exposed to Marek's disease virus by direct contact. Marek's disease-free chicken follicular tissues were antigen-negative. Testis, ovaries, liver, spleen, kidney, heart, brain, bursa and bone marrow preparations from Marek's disease-infected chickens did not harbor MDHV antigen. Normal chicken serum and serum containing antibodies to Rous sarcoma virus did not react with the follicular tissue MDHV antigen. Marek's disease antibodies were found in sera from some but not all chickens with and without gross pathology which had been infected with MDHV. Antigens extracted from virus-containing follicular epithelial cells growing *in vivo* or *in vitro* were of a similar nature. Chicken sera positive for Marek's disease antibodies caused specific coating of MDHV particles.

1966 EXPERIENCES WITH COMPLEMENT FIXING SERA FROM PIGEONS IN AVIAN LEUKOSIS. (E.) Watanabe, M. (Natl. Inst. Anim. Hlth., Tokyo, Japan). *Bibl Haemat* 36:183-191, 1970.

Inoculation of pigeons with the Schmidt-Ruppin (S-R) strain of Rous sarcoma virus produced tumors approximately 10 days postinoculation; complement fixing (CF) antibodies to Rous sarcoma virus appeared in pigeon sera by 30 days after inoculation. Tumors regressed by 70 days postinoculation, and the inoculated pigeons were resistant to subsequent injections of S-R virus. While tumor incidence in pigeons inoculated with S-R virus attained 100%, Bryan's standard strain and Bryan's high titer strain of Rous virus produced only a 50% tumor incidence. Birds not developing tumors did not produce detectable CF antibody to Rous sarcoma virus. S-R virus, but not Bryan virus strains, produced foci on pigeon embryo cell monolayers. The presence of CF antigen to Rous sarcoma virus could be used to distinguish chickens with acute lymphomatosis from chickens with Marek's disease.

1967 VIRAL ANTIGENS IN THE BAI STRAIN A (AVIAN MYELOBLASTOSIS) VIRUS ASSOCIATED MYELOBLASTS AND CHICK EMBRYO FIBROBLASTS. (E.) Rao, P. R. (Postgrad. Ctr., Marangal, India). *Curr Sci* 40(4):81-83, 1971.

Chick embryo fibroblast cultures were infected with a multiplicity of 100 avian myeloblastosis virus particles/cell; myeloblast cells of leukemic chickens were used to prepare soluble fractions which were reacted with antisera against avian myeloblastosis virus and group specific hamster antiserum for 48-72 hr. The myeloblast soluble fraction revealed 2 precipitin lines with the hamster serum, one of which showed identity with the respective single lines observed with chick tissue-absorbed sodium deoxycholate and sodium dodecyl sulfate rabbit sera. Unabsorbed sodium deoxycholate chick tissue showed 2 distinct and 1 very faint line formed against the unabsorbed sodium dodecyl sulfate rabbit serum; only 1 of the lines formed against both unabsorbed sera was continuous with the single line produced against the absorbed sera. In comparison, only 1 precipitin line formed against all sera and each line showed identity with the next one in the case of fibroblast soluble fraction. These results indicated a difference between the viral antigens present in the myeloblast and fibroblast cells despite infection with the same virus.

1968 IMMUNIZATION BY THE RADIATION LEUKEMIA VIRUS. (E.) Harari-Ghera, N. (Weizmann Inst. Sci., Rehovoth, Israel). *Bibl Haemat* 36:261-266, 1970.

Mice were immunized by inoculation with 10⁻²-10⁻⁵ dilutions of radiation leukemia virus (virus obtained from non-leukemic tissues of irradiated mice) and subsequently challenged with leukemic cell isotransplants. One million leukemic cells injected 30 days

after inoculation with radiation virus failed to grow in mice immunized by radiation virus dilutions of 10^{-2} and 10^{-3} injected directly into the thymus, while a 95% tumor cell take was seen in the control group of non-immunized mice. Non-immunized mice given leukemic cell isografts and 400 r whole body irradiation 2 days later showed 100% tumor cell takes. Mice immunized with radiation virus were rendered resistant to leukemic cell challenge at about 2 wk after radiation virus inoculation into the thymus, and this immunity was maintained for as long as 12 wk. Removal of the thymus after immunization with radiation virus did not impair the immunity of immunized mice. Immunization with radiation virus also protected mice against development of lymphoma; an 18% lymphoma incidence was observed following immunization with radiation virus, while nonimmunized mice given whole body irradiation developed lymphoma in 85% of cases.

- 1969 ACTIVITIES OF IMMUNE LYMPHOID CELLS AGAINST LEUKEMIA VIRUS-CARRIER MURINE NEOPLASTIC CELLS. (E.) Sinkovics, J. G. (U. Texas M. D. Anderson Hosp. Tumor Inst. Houston), R. J. Pienta, M. J. Ahearn, J. M. Trujillo and F. M. Mikulik. *Bibl Haemat* 36:618-623, 1970.

Immune lymphocytes were drawn from Swiss mice which rejected implants of lymphoma or sarcoma cells carrying Rauscher leukemia virus antigens. These lymphocytes could not suppress the growth of lymphoma or sarcoma cells *in vitro*. In contrast, delayed growth of tumors and in some cases complete rejections of tumors were observed in mice inoculated with immune lymphocytes mixed with sarcoma or lymphoma cells in proportions of 200 immune lymphocytes to 1 neoplastic cell. Normal lymphocytes failed to impair tumor growth *in vivo*.

- 1970 IMMUNOLOGICAL AND GENETIC FACTORS IN MURINE VIRUS-INDUCED LEUKEMIA. (E.) Chieco-Bianchi, L. (Div. Cancer Res., U. Padua, Italy), D. Collavo, N. Pennelli and G. Tridente. *Bibl Haemat* 36:234-239, 1970.

One group of 1- to 3-day-old mice of C3Hf/Gs (H-2^k), C57BL(H-2^b) and (C3Hf/Gs x C57BL)F1 strains were injected s.c. with 0.05 ml of 20% cell-free extract from C3Hf/Gs mice with passage A Gross virus-induced primary leukemia; a second group of adult C3Hf/Gs and F1 hybrids, both neonatally virus-injected and normal, were given i.p. repeated injections of dilute cell-free leukemic extract containing passage A Gross virus for the preparation of sera against target C3Hf/Gs passage A leukemic cells. Results showed that while serum from C3Hf/Gs mice that were neonatally virus-injected and immunized when adults contained practically no antibodies, the serum from C3Hf/Gs mice receiving no virus neonatally but immunized when adults showed significant antibody titers. Sera taken from 2 F1 hybrid groups exhibited a remarkably similar cytotoxic activity regardless of the fact that one group had been treated with virus neonatally and the other group remained untreated.

All these sera were devoid of detectable cytotoxicity when tested on normal C3Hf/Gs cells as were sera from normal C3Hf/Gs and F1 hybrid donors when tested on leukemic C3Hf/Gs cells. The oncogenic effect of passage A group virus was neutralized by sera from both C3Hf/Gs and F1 hybrid mice which had received virus when adults; serum from F1 hybrids neonatally virus-injected and immunized when adults was equally effective and showed a remarkable decrease in leukemia incidence in the test animals; serum from C3Hf/Gs mice, neonatally injected with virus and subsequently immunized did not neutralize the oncogenicity of the virus.

- 1971 THE ACTION OF DNA ANTAGONISTS ON EPSTEIN-BARR VIRUS (EBV)-ASSOCIATED EARLY ANTIGEN (EA) IN BURKITT LYMPHOMA LINES. (E.) Gergely, L. (Karolinska Inst., Stockholm, Sweden), G. Klein and I. Ernberg. *Int J Cancer* 7(2):293-302, 1971.

The effect of cytosine arabinoside (200 μ g/ml and iododeoxyuridine (1-100 μ g/ml) on Epstein-Barr virus-associated antigens was studied in two Burkitt lymphoma-derived carrier culture lines by combined immunofluorescence and autoradiography (³H-thymidine). Early antigen (EA)-positive cells accumulated in treated cultures at a concentration 5-40% in response to both drugs compared to 2% in untreated cultures; cytosine arabinoside blocked production of viral capsid antigen more effectively than iododeoxyuridine, and in both lines virtually all viral capsid antigen positive cells were EA-antigen positive also. It has been suggested that EA is a prerequisite for viral capsid antigen.

- 1972 ANTIBODIES TO EPSTEIN-BARR VIRUS IN A BURKITT'S LYMPHOMA CELL LINE IN TAIWAN MONKEYS (*MACACA CYCLOPIS*). (E.) Chu, C. T., (Coll. Med., Natl. Taiwan U., Formosa), C. S. Yang and A. Kawamura, Jr. *Appl Microbiol* 21(3):539-540, 1971.

Indirect immunofluorescence tests indicated that of 273 adult Taiwan monkeys (*Macaca cyclopis*) 193 or 70.7% harbored anti-Epstein-Barr virus antibody at titers of 1:10 or less, while 1 had a titer of 1:640. Healthy persons in Taiwan had a peak anti-Epstein-Barr virus antibody titer of 1:160. To determine the persistence of maternal anti-Epstein-Barr virus antibody in baby Taiwan monkeys, blood specimens were collected at 5 wk intervals from 6 monkeys which had been separated from their mothers at birth and fed artificially. Two baby monkeys had low antibody titers for 50 wk, indicating a long persistence of the maternal antibody in some cases.

- 1973 ANTIBODIES TO EARLY EPSTEIN-BARR VIRUS-INDUCED ANTIGENS IN BURKITT'S LYMPHOMA. (E.) Henle, G. (Child. Hosp. Philadelphia, Pa.), W. Henle, G. Klein, P. Gunven, P. Clifford, R. H. Morrow and J. L. Ziegler. *J Nat Cancer Inst* 46(4):861-871, 1971.

Antibodies to early Epstein-Barr virus-induced antigens (EA) and other Epstein-Barr virus-related antigens were compared, and the significance of anti-Epstein-Barr antigens in Burkitt's lymphoma was investigated in sera from African patients with clinically and histologically confirmed Burkitt's lymphoma. The results of EA tests showed positive reactions in sera which had anti-Epstein-Barr virus-related antigen titers of at least 1:40; however, sera with titers of this magnitude of anti-Epstein-Barr virus-related antigen did not always contain the EA antigen. Not every patient with Burkitt's lymphoma had antibodies to EA antigen and of 17 patients admitted without detectable antibodies, 59% survived for one year; of those who had titers greater than 1:40 at admission, only 28% survived a year. Most sera obtained shortly before death had high titers in contrast to those who had survived for 2 yr or longer in which the antibody was lacking or the titer was low. The differential responses of Burkitt's lymphoma patients remains unexplained.

974

SEROEPIDEMIOLOGIC STUDIES OF EPSTEIN-BARR VIRUS ANTIBODY IN MONKEYS. (E.)

Anderson, J. C. (Bionetics Res. Lab., Inc., Kensington, Md.) and L. B. Malan. *J Nat Cancer Inst* 46(4): 881-884, 1971.

Indirect immunofluorescence tests were performed on sera from a colony of Macaque monkeys (*Macaca mulatta* and *M. fascicularis*) to detect the presence of antibodies to the Epstein-Barr virus in these animals. All adult breeder monkeys had positive antibody titers; all of 30 newborn monkeys had positive antibody titers. However, the number of animals having positive titers dropped as the age of the monkeys tested increased; 3% of 3-month-old animals and less than 5% of 8-10-month-old animals had positive antibody titers. No antibody was found in macaques 18-20-month old. Of 10 4-yr-old macaques tested, 3 had positive antibody titers. Seronegative monkeys exposed to the breeding colony of monkeys showed positive virus antibody titers in 3 of 20 cases within 6 months of exposure.

975

SEROLOGICAL STUDIES OF THE FELINE LEUKEMIA VIRUS. (E.)

Hardy, W. D., Jr. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), G. Geering, J. J. Old, E. De Harven, R. S. Brodey and S. K. McDonough. *Bibl Haemat* 36:343-354, 1970.

Antiserum to group-specific antigen of feline leukemia virus was prepared in a female New Zealand white rabbit from tissue washings and pleural fluid of a male domestic cat with lymphosarcoma; antisera to murine leukemia virus group-specific antigens were prepared in rats with Gross virus-induced leukemia transplants of an inbred rat. After suitable absorption, the rabbit anti-feline leukemia virus serum reacted with antigen present in tissue extracts from 75% of lymphomatous cats and in the salivary glands of 4 of the 33 lymphomatous cats tested. In control tissue extracts from 46 normal cats and cats with diseases

other than lymphosarcoma, feline leukemia virus antigen was detected in the tissue extracts of one ostensibly healthy cat; 5 of 13 cases of infectious peritonitis possessed the antigen, and 2 cats with spontaneous fibrosarcoma contained the antigen and C-type virus particles. Neoplastic tissues from 2 dogs with lymphosarcoma after receiving feline leukemia virus at birth demonstrated the antigen and budding leukemia virus. Other species examined including dog, cow, pig, goat and man were negative for the presence of the antigen. The milk of 27 normal lactating cats was also negative for feline leukemia virus antigen.

1976

COMPARATIVE STUDIES OF FELINE AND HUMAN LEUKEMIA BY MIXED HEMADSORPTION REACTION.

(E.) Maruyama, K. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), L. Dmochowski and C. G. Rickard. *Bibl Haemat* 36:355-367, 1970.

Two tissue culture cell lines (F-491 and F-503) derived from bone marrow specimens of cats with virus-induced lymphoma and a culture cell line (FE-4) derived from a normal cat embryo and treated with a cell-free filtrate of homogenate of tumor tissue from a Siamese cat with spontaneous lymphoma, as well as cell lines derived from human embryonic kidney and infected *in vitro* with Rauscher leukemia virus, human embryonic skin and whole human embryo, were used to study the hemadsorption reaction with anti-murine leukemia virus immune sera and with human sera. Results of mixed hemadsorption tests and electron microscopy of feline cell cultures from virus-induced lymphomas were positive with anti-murine leukemia virus, anti-Rauscher leukemia virus (monkey), and anti-rat-adapted Friend leukemia virus; numerous type C particles and budding appeared in the cultures. Controls were negative when tested with anti-murine leukemia virus serum and one culture gave positive results with anti-Rauscher leukemia virus monkey serum and anti-rat-adapted Friend leukemia virus rabbit serum; a small number of type C particles were found in this last culture by electron microscopy. The results of tests of feline cell cultures with human sera showed the incidence of positive tests to be higher with sera from normal individuals than with sera from patients with leukemia, lymphoma or other neoplastic diseases, with no significant difference between virus-infected cultures and a control non-infected culture. Both monkey and mouse immune sera against mouse Rauscher leukemia virus gave positive reactions at titers of 1:1024 and 1:256, resp., when tested with virus-infected human embryo kidney cells; control tissue gave negative reactions. Rabbit immune serum against rat-adapted Friend leukemia virus was also positive at a titer of 1:256 with the infected cell line, but negative with the non-infected cell line. Monkey immune serum against HeLa cells gave a titer of 1:2048 with both culture lines, while mice immune sera against feline embryo cultures infected with feline lymphoma virus were positive with both infected and uninfected human cultures; numerous type C particles and budding were found in the infected culture. Three of 20 sera of leukemia patients of various types gave positive reactions when tested against Rauscher leukemia virus-infected human embryo kidney cells at a titer varying from 1:8 to 1:32, whereas none of the 20 normal donor sera gave positive reactions.

IMMUNOLOGY

- 1977 FELINE LEUKEMIA VIRUS: DETECTION OF GROUP-SPECIFIC VIRAL ANTIGEN AND INFECTIOUS VIRUS BY A COMPLEMENT FIXATION TEST. (E.) Sarma, P. S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), J. F. Baskar, R. J. Huebner, L. J. Old and W. D. Hardy, Jr. *Bibl Haemat* 36:368-378, 1970.

Hyperimmune antiserum prepared in rabbits with ether-disrupted feline leukemia virus was used to detect complement fixation antigens in feline lymphosarcoma, osteosarcoma and fibrosarcoma tissues; this test was utilized for detection of the replication of feline leukemia and sarcoma viruses in susceptible feline embryo fibroblast cultures. Feline embryo fibroblast cultures inoculated with field specimens of feline lymphosarcoma such as clarified tissue extracts, clarified body fluids, and partially purified tumor concentrates developed antigen titers of 1:4 to >1:32 within 10-12 days after viral inoculation, whereas parallel uninoculated control cultures failed to react with rabbit antiserum (titer 1:4). Electron microscopy and radioisotope labeling techniques gave parallel results.

- 1978 INACTIVATION OF T ANTIGEN-FORMING CAPACITIES OF SIMIAN VIRUS 40 AND ADENOVIRUS 12 BY ULTRAVIOLET IRRADIATION. (E.) Yamamoto, H. (Natl. Inst. Hlth., Tokyo, Japan), and H. Shimojo. *J Virol* 7(4):419-425, 1971.

Monolayers of primary or secondary cultures of green monkey kidney cells and human embryonic kidney cells were inoculated with 0.2 ml of UV-irradiated or non-irradiated simian virus 40 and adenovirus 12, resp. After adsorption at 36°C for 2 hr, the cell cultures were incubated at 36°C for 72 hr (simian virus 40) or 48 hr (adenovirus 12) in medium containing cytosine arabinoside, the number of cells were counted under a fluorescence microscope and later examined again following incubation with anti-simian virus 40 serum. The appearance of T antigen-positive cells was slower in cultures infected with UV-irradiated viruses than with unirradiated viruses. The percentage of T antigen-positive cells in green monkey kidney cells for all cells increased up to 72 hr postinfection and then remained unchanged whereas in human embryonic kidney cells, T antigen-positive cells increased up to 48 hr and then decreased. A linear relationship was always observed in repeated experiments when the percentage of T antigen-positive cells was less than 10% in the dose-response curve. In contrast to the unirradiated virus, irradiated virus of both groups induced T antigen in more cells than expected when cells were infected with lower dilutions of virus suggesting that multiplicity reactivation may have occurred in cells infected with UV-irradiated virus at a higher multiplicity. Irradiation of the viruses resulted in inactivation of T antigen-forming capacities of both viruses at the same rate as their infectivities.

- 1979 ATTEMPTS OF IMMUNIZATION AGAINST TUMORS INDUCED BY SV40 VIRUS IN HAMSTERS. (Fr.) Ciobanu, Z. (Dr. I. Cantacuzino Inst., Bucharest, Rumania) and A. Fenyves. *Arch Roum Path Exp Microbiol* 29(1-2):109-116, 1970.

Hamsters immunized by SV40-transformed and irradiated hamster cells developed tumors in 87.5% of cases following challenge with cells from tumors induced in hamsters by inoculation of transformed cells or of SV40. Hamsters immunized with a high-titer strain of SV40, by contrast, developed tumors in only 30% of cases following tumor cell challenge. Thirty to ninety day-old hamsters given a highly tumorigenic dose of SV40 at birth were rendered almost completely immune to tumor development by 1 or 2 doses of the high-titer virus. Immunization of female hamsters 1-3 months before parturition with the high titer SV40 protected their offspring from tumor induction by SV40 injection.

- 1980 STUDIES ON NONDEFECTIVE ADENOVIRUS-SIMIAN VIRUS 40 HYBRID VIRUSES: I. A NEWLY CHARACTERIZED SIMIAN VIRUS 40 ANTIGEN INDUCED BY THE Ad2⁺ND₁ VIRUS. (E.) Lewis, A. M., Jr. (Natl. Inst. Allerg. Infect. Dis., Natl. Inst. Hlth Bethesda, Md.) and W. P. Rowe. *J Virol* 7(2):189-197, 1971.

The distribution of simian virus 40 (SV40) "U" antibody (heat-stable) in hamsters bearing SV40 induced tumors and the induction of the U antigen by the nondefective adenovirus 2-SV40 hybrid virus (Ad2⁺ND₁) and SV40 viruses was studied in weanling hamster kidney cell cultures and SV40-transformed human fibroblasts by complement fixation. In tumor-bearing animals, antibodies to SV40 T antigen first appeared when tumors were 10-25 mm in diameter and antibody to SV40 U antigen developed 1-3 wk later. At 100 days after injection when the tumors were 40-50 mm in diameter, T antibody titers were between 1:40 and 1:320, whereas U antibody titers ranged from less than 1:10 to 1:160. Cells infected with or transformed with SV40 contained 4-64 units of heat-stable SV40 antigen which reacted only with the T⁺ U⁺ hamster pool and 16-128 units of heat-labile SV40 T antigen which reacted with both T⁺ U⁺ and T⁺ U⁻ serum pools. In response to treatment with cytosine arabinoside and heat adenovirus 2 V antigen was completely inhibited, and the appearance of SV40 U antigen in hybrid cells was delayed for approximately 4 hrs; the number of cells containing the antigen was reduced 20-fold. Since SV40 U antigen is present in both tumors and transformed cells, it could be involved in SV40-mediated transformations.

- 1981 IMMUNOFLUORESCENT STUDIES OF ANTIGENS INDUCED BY ADENOVIRUS TYPE 12. (E.) Srivastava, P. (Med. Coll. Georgia, Augusta) and S. S. Lefkowitz. *Proc Soc Exp Biol Med* 136(4):1133-1140, 1971.

Guinea pigs were immunized sequentially with purified adenovirus type 12 and equal amounts of complete Freund's adjuvant as a first injection and incomplete Freund's adjuvant as a second injection 1 wk later. They were bled 2 wk following the final injection as a source of antibody to viral antigens while antisera to T antigens were obtained from hamsters bearing either transplanted or virus-induced tumors.

La cells infected with adenovirus type 12 were sensitive for T antigens as determined by immunofluorescent techniques 6 hr after viral adsorption primarily within the nuclei of infected cells, with smaller amounts appearing within the cytoplasm. The number of cells and the intensity of fluorescence increased until 24 hr postinfection followed by a decrease by 72 hr. A second type of fluorescence, termed fluorescent dots, was first noted 16-18 hr after viral infection only in the nuclei of infected cells and were morphologically distinct from the dots previously reported. Fluorescence intensity and the number of cells affected became maximal by 48 hr, followed by a decrease again at 72 hr. Viral antigens were first noted within the nuclei of infected cells at 18-20 hr and gradually increased in size until the nuclei became filled with large amounts of the brilliantly stained antigens. A fourth antigen, the fluorescent membranes, was not found at 48 hr after viral infection but could be detected at 72 hr; the number of cells demonstrating this antigen increased up to 72 hr. No specific fluorescence was seen in control preparations, although some faint autofluorescence was noted. Most of the hamster sera reacted with antigens; however, less than 50% of these sera reacted with the exclusively intranuclear antigen and the antigen found at the cell membrane.

2 CONCOMITANT IMMUNITY IN HAMSTERS BEARING SYNGENEIC TRANSPLANTS OF TUMORS INDUCED BY PARA-ADENOVIRUS 7, SIMIAN ADENOVIRUS 7, 9,10-DIMETHYLBENZANTHRACENE. (E.) Lausch, R. N., Milton S. Hershey Med. Ctr. Pennsylvania St. U., Hershey) and F. Rapp. *Int J Cancer* 7(2):322-330, 1971.

Animals were induced in mice by s.c. injection of 2-dimethylbenz(a)anthracene (DMBA) or simian adenovirus 7 (SA7) and transplanted into other mice; 1 wk thereafter, transplant-bearing mice were given a second transplant of DMBA- or virus-induced tumor cells to test the resistance to the second transplant conferred on the mice by the first transplant. In mice bearing palpable DMBA-induced tumor transplants which were challenged 1 wk later by DMBA-induced tumor cells, the growth of the second transplant was delayed and the number of cells required to produce tumors in 50% of mice was 10 times greater than in tumor-free controls. Although the initial tumor transplant apparently rendered mice immune to subsequent transplants, the primary tumor transplant grew progressively in these mice. In a related experiment, a less transplantable DMBA-induced tumor line was inoculated into mice prior to challenge with cells of the same tumor; the total tumor incidence produced by s.c. injection with tumor cells in tumor-free mice was 58%, while that in mice already inoculated with tumor cells was 13%. Resistance to a second tumor transplant was found to be specific with tumor cells induced by SA7 virus and A-adenovirus 7 and DMBA-induced tumor cells.

3 PASSIVE TRANSFER OF TUMOR-SPECIFIC RESISTANCE TO METHYLCHOLANTHRENE-INDUCED SARCOMAS IN RATS. (E.) Ishikawa, Y. (Hiroshima U. Sch.

Med., Japan), M. Fukushima, T. Sato, M. Komaba, H. Yagihashi, A. Hokama and M. Kojika. *Tohoku J Exp Med* 103(2):195-201, 1971.

Sarcomas were induced in rats by s.c. injections of methylcholanthrene (10 mg); tumors were excised, and the tumor cells were injected into the same rats from which they had been taken, as well as into another group of rats (the donors). Sensitized spleen cells were prepared from these donor rats, and spleen cell supernates were injected i.p. into the rats whose tumor cells had originally been used to sensitize the donors. The antitumor activity of the splenic supernate was judged by the number of days from the time of excision of the original tumor to the death of the rat. Control rats (those given injections of tumor cells immediately after excision of the original methylcholanthrene-induced tumor, but not given spleen cells from sensitized donors) showed survival times of 27-47 days; the average weight of excised tumors at the death of these rats was about 3 g. Rats given sensitized spleen cells had survival times of 22-101 days, and final tumor weights of about 3 g. The survival of sensitized spleen cell-recipient rats was significantly prolonged relative to the survival of controls.

1984 IMMUNOTHERAPY EXPERIMENTS WITH A METHYLCHOLANTHRENE-INDUCED GUINEA PIG LIPOSARCOMA. (E.) Eilber, F. R. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), E. C. Holmes and D. L. Morton. *J Nat Cancer Inst* 46(4):803-808, 1971.

The effect of intradermal immunization with syngeneic tumor cells on the growth of methylcholanthrene-induced liposarcoma was studied in strain-2 guinea pigs. Immunization with viable tumor cells inadequate to produce progressively growing tumors with or without Bacillus Calmette-Guerin (BCG) as an adjuvant completely prevented the subsequent growth of the i.m. challenge tumor. In contrast, 88% of the nonimmunized controls developed progressively growing tumors. Prior sensitivity to BCG did not affect the subsequent growth of intramuscular tumor cells. Viable cells from grafts of the transplanted tumor, irradiated tumor cells and tumor cells grown in tissue culture were effective as immunogens. These studies indicated that tumor-specific transplantation antigens can be used for immunotherapy of a chemically induced sarcoma in syngeneic guinea pigs. Use of these antigens for clinical immunotherapy of patients with a limited number of residual tumor cells is at least theoretically possible.

1985 CROSS-REACTING TUMOR-SPECIFIC TRANSPLANTATION ANTIGENS IN METHYLCHOLANTHRENE-INDUCED GUINEA PIG SARCOMAS. (E.) Holmes, E. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), D. L. Morton, G. Schidlovsky and E. Trahan. *J Nat Cancer Inst* 46(4):693-700, 1971.

The characteristics of tumor-specific transplantation antigens in methylcholanthrene (MCA)-induced guinea pig sarcomas were studied utilizing electron microscopy. Animals immunized by temporary growth with either

IMMUNOLOGY

MCA-A or MCA-C liposarcomas resisted both MCA-A or MCA-C liposarcomas when simultaneously challenged with these tumors with no MCA-A tumor takes and only 1 MCA-C tumor take occurring in 6 immunized guinea pigs, compared to 100% incidence growth in untreated control animals. However, in all MCA-A and MCA-C resistant guinea pigs tumor MCA-25 grew progressively, indicating that MCA-25 contained an individually distinct tumor-specific transplantation antigen, whereas MCA-A and MCA-C contained similar tumor-specific transplantation antigens. Electron microscopic examination revealed virus-like particles in the tumor cells of MCA-A and MCA-25 but failed to reveal any in MCA-C cells.

- 1986 TUMOR-SPECIFIC ACTIVE ENHANCEMENT OF A MURINE SARCOMA. (E.) Bloom, E. T. (Dept. Med. Microbiol. Immunol., U. California, Davis) and W. H. Hildemann. *Tissue Antigens* 1(1):5-13, 1971.

Mice of the C57Bl/10 strain were immunized with 10^6 viable sarcoma cells from a mouse sarcoma induced by 3-methylcholanthrene and subsequently challenged with inocula of sarcoma cells of the same type. Growth of transplanted sarcoma cells in preimmunized animals was much accelerated compared to the growth of sarcomas in unsensitized mice; by day 15 after challenge with sarcoma cells, mean tumor volumes in unsensitized mice were 0.42 cc and in preimmunized mice were 0.98 cc; the relative figures for tumor volume in sensitized and control mice on day 27 were 5.0 and 2.5 cc, resp. It was shown that the accelerated tumor growth following pre-immunization was tumor-specific and not a result of non-specific weakening of the host defenses. The growth of sarcomas could also be enhanced by pretreating mice with anti-sarcoma antiserum. Enhancement of tumor growth was more consistently induced in male than in female mice.

- 1987 INFLUENCE OF AMOUNT OF ANTIGEN ON IMMUNITY INDUCED BY SPECIFIC ANTIGENS OF SOLID SYNGENIC MOUSE TUMORS. (Fr.) Donner, M. (Res. Unit Exp. Cancerology, Tumoral Radiobiol., Vandoeuvreles-Nancy, France) and C. Burg. *C R Soc Biol* 164(8-9): 1832-1836, 1970.

Rhabdomyosarcomas RV₂ and CB 1 were induced by methylcholanthrene, resp., in male and female C₃H/He mice which were then immunized by s.c. inoculation of 2×10^{-3} mg to 500 mg tumor fragments sterilized by X-irradiation. RV₂ tumors occurred in about 80% of the animals. There was a perceptible diminution in rate of tumor formation after immunization with 500 mg of irradiated tumor cells. Mean survival and mean tumor diameter showed no significant differences in the various animal groups. In animals with CB 1 tumors, the degree of immunization varied with the dose of irradiated tumor tissue. Optimal resistance occurred at doses in the neighborhood of 1 mg. When the dosage was greater than 1 mg, tumor growth increased significantly compared to untreated animals. Survival of the immunized animals was not significantly different from untreated animals.

- 1988 TRANSFER OF TUMOR-SPECIFIC IMMUNITY WITH RNA: INHIBITION OF GROWTH OF MURINE TUMOR ISOGRAFTS. (E.) Ramming, K. P. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and Y. H. Pilch. *J Nat Cancer Inst* 46(4):735-750 1971.

C3Hf/HeN mice were injected in the right hind limb with 0.1 ml of tumor cell suspensions from BP-1 or BP-4 benzopyrene-induced sarcomas, and the limb was amputated after tumor formation. Ten days post-amputation, the mice were given s.c. injection of 10^4 viable cells of the same tumor used for immunization, while normal mice received 10^4 BP-1 or BP-4 sarcoma cells as controls. Extracts rich in RNA were prepared from spleens and lymph nodes of Hartley guinea pigs 10-14 days after immunization with C3H BP-4 sarcoma and labeled; groups of 20-30 normal C3H/HeN mice were challenged with i.p. injections of 0.5 ml spleen cells incubated with a) RNA from lymphoid tissues of guinea pigs immunized with BP-4 mouse sarcoma (BP-4 RNA); b) RNA from guinea pigs immunized with BP-1 sarcoma (BP-1 RNA); c) RNA from pigs immunized with normal C3H tissues (normal tissue RNA); d) RNA from pigs given Freund's adjuvant only (Freund's adjuvant RNA); e) BP-4 RNA treated with ribonuclease; f) BP-4 RNA treated with deoxyribonuclease; or g) BP-4 RNA treated with pronase. Tumor incidence in mice challenged with tumor cells similar to immunization amounted to 0% and 9% for BP-4 and BP-1 sarcoma cells, resp., compared to controls of 78% and 97% tumor incidence, resp., whereas those challenged with tumor cells BP-1 and immunized against BP-4 and vice versa showed a tumor incidence of 79% and 77% and in controls, 87% and 75% resp. Recipients of spleen cells incubated with BP-4 RNA had a significantly lower incidence of tumor development than did mice in any other group; spleen cells incubated with RNA from guinea pigs immunized with normal C3H mouse tissues did not inhibit tumor development; those receiving spleen cells incubated with RNA from pigs immunized with Freund's adjuvant alone did not evidence decreased tumor incidence. Similar results occurred with injection of syngeneic spleen cells alone, whereas those receiving cells incubated with BP-4 RNA ribonuclease-treated preparation had a tumor incidence similar to that of the challenge controls. Inactivation did not occur in response to treatment with deoxyribonuclease or pronase.

- 1989 SYNERGISTIC IMMUNODEPRESSIVE EFFECT OF 7,12-DIMETHYLBENZ[a]ANTHRACENE AND URETHAN IN THE RAT. (E.) Perocco, P. (Inst. Gen. Path., Bologna, Italy), C. Franceschi, A. T. Di Marco and G. Prodi. *Proc Soc Exp Biol Med* 136(4):1024-1026 1971.

The effects of combined doses of 7,12-dimethylbenz[a]anthracene (DMBA) and urethan on the hemagglutination titers achieved by the rat immune system in response to human red blood cell antigen were investigated. Male rats were given i.p. doses of DMBA (5-50 µg, body wt) followed by 6 successive i.m. doses of urethan (0.1-1.0 mg/g body wt); 8 days after the beginning of treatment, rats were given 1 ml/100

dy wt of human RBC. Neither DMBA nor urethan affected the hemagglutinin response of the rats to the antigen; control rats not given carcinogen showed hemagglutinin titers of 7.70 (\log_2 of the inverse of the maximum dilution showing an appreciable hemagglutination), and rats given either carcinogen alone showed titers of 7.40-7.55. DMBA and urethan administered concurrently, however, depressed the hemagglutination titers; larger doses of carcinogens produced more marked depression of the response. Rats given 25 $\mu\text{g/g}$ DMBA and 0.5 mg/g urethan showed hemagglutinin titers of 3.80. Double treatment with carcinogens failed to prolong the survival of skin grafts against a weak histocompatibility barrier.

1990 THE ANTIGENICITY OF RAT MAMMARY TUMOURS INDUCED BY 7,12-DIMETHYLBENZ(a)ANTHRACENE.

(E.) Kellen, J. A. (Banting Inst., U. Toronto, Ontario, Canada) and K. M. Anderson. *Oncology* 18(1):49-54, 1971.

The antigenic properties of a histologically diverse group of 7,12-dimethylbenz(a)anthracene-induced rat mammary gland tumors were studied by means of double-diffusion agar techniques. Antisera harvested from immunized rabbits showed effective titers persisting for a period not exceeding 3 wk; the unabsorbed sera reacted with all 17 tumor extracts, usually within 24 hr in sharp precipitation bands with a single line appearing followed by a second, and sometimes a third. The reactivity of the antisera had no relation to the tumor size, rate of growth and histopathology. No cross-reaction with normal rat organs or serum occurred.

1991 MORPHOLOGICAL AND IMMUNOCHEMICAL STUDIES OF RAT GLIAL TUMORS AND CLONAL STRAINS PROPAGATED IN CULTURE. (E.) Benda, P. (Massachusetts Gen. Hosp., Boston), K. Someda, J. Messer and W.H. Sweet. *J Neurosurg* 34(3):310-323, 1971.

The establishment of stable permanent lines of transplantable glial tumors induced in Wistar strain and C.D. Fisher rats by injections of N-nitrosomethylurea were studied by means of culture propagation and light, phase and electron microscopic techniques. Within a few days after the start of N-nitrosomethylurea injections, between 17-43 wk after termination of injections, primary brain tumors and 3 schwannomas were found among 60 Wistar rats and 3 primary and 1 s.c. type have been successfully maintained in culture for 3 yr. Among 48 C.D. Fisher rats, 10 primary brain and 1 primary cord tumor were found; 7 of these were successfully subcultured over a period of a yr. Inoculation of dispersed cell aliquots (106 cells) from each of the 11 lines into newborn rats resulted in visible localized tumor within 2-3 wk under the skin, muscle, or in the peritoneal cavity according to the site of injection with no evidence of metastases. In C.D. Fisher rats, neoplasms rapidly increased in size, were firm and had a homogeneous texture under a scalpel capsule; in Wistar rats necrosis occurred centrally with or without fluid formation as the necrosis extended, and after intracranial injection

the brain section surface was covered by an extensive tumor mantle. Primary tumors were generally composed of undifferentiated cells with tumor satellitosis, while secondary tumors varied according to the site of inoculation. The distinctive neural protein called "S-100" was detected in soluble extracts of cultured cells from both primary and secondary tumors. If the cloned cultures maintain relative invariability of growth rate and degree of differentiation the value of this rat model in the study of the metabolism, radio-sensitivity, and chemotherapy of gliomas will exceed that of any others currently known.

1992 TUMOR IMMUNITY: IMPAIRMENT IN TUMOR-BEARING HOSTS. (E.) Bernstein, I. D. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), H. T. Wepsic, B. Zbar and H. J. Rapp. *J Nat Cancer Inst* 46(4):873-880, 1971.

Strain-2 guinea pigs were initially immunized against a diethylnitrosamine-induced hepatoma by inoculation with living hepatoma cells; ascites and solid tumors of 3 different lines were used. Cell-mediated systemic tumor immunity was transferred passively from immunized donors to unimmunized syngeneic recipients by inoculating guinea pigs with peritoneal exudate from immunized animals following an initial tumor-inducing dose of tumor cells prior to tumor cell challenge. While tumor-bearing animals showed immunity toward the tumor cell challenge, this immunity, in terms of tumor growth suppression, was significantly less than that of passively immunized tumor-free animals. The impairment of the immune response in tumor-bearing guinea pigs was seen in animals bearing tumors with differing antigenicities. Serum from animals bearing large tumors had no effect on passively transferred tumor immunity. It is believed that successful transfer of systemic tumor immunity depends on factors contributed by the recipient of the tumorigenic transplant.

1993 SURVIVAL OF TUMOURS AFTER IMMUNIZATION AGAINST OESTROGENS (E.) Caldwell, B.

V. (Yale U. Sch. Med., New Haven, Conn.), S. A. Tillson, H. Esber and I. H. Thorneycroft. *Nature* 231(5298):118-119, 1971.

Female rats bearing transplanted estrogen-dependent mammary adenocarcinoma were immunized against estrogens by injection of 1 mg of estradiol-17 β -hemisuccinate; immunizations were performed once a wk for 4 wk with 1 booster injection 4 wk later. The time between implantation of tumor and first signs of tumor growth was 36 days in rats not given active estrogen immunization and 50 days in immunized rats. Immunized rats had a survival time of 100 days compared with a survival time of 60 days for unimmunized rats. Rats showing the highest titers of anti-estrogen antibodies had the longest survival times.

1994 IMMUNOCHEMICAL STUDIES ON ANTI-4-AZOQUINOLINE-1-OXIDE ANTIBODY. (E.) Nakashima, S. (Fac. Pharm. Sci., Toyama U., Gofuku, Japan). *J Biochem* 69(3):605-607, 1971.

Rabbit serum protein was conjugated with diazotized 4-aminoquinoline-1-oxide, and rabbits inoculated with the conjugate yielded antisera containing antibodies to the conjugate. A quantitative precipitation reaction between the rabbit serum protein-4-aminoquinoline-1-oxide conjugate and anti-conjugate antibody was performed. Of the 2 antibody-containing antisera prepared, one precipitated 100 µg of conjugate equal to 14 mg of antibody, and the other precipitated 50 µg of conjugate to equal 10 mg of antibody. 4-Nitroquinoline-1-oxide itself inhibited the precipitation of conjugate by antibody. When 4-nitroquinoline-1-oxide was added to the antibody-conjugate mixture, the amount of precipitate was reduced by 20%. Gel filtration and 2-mercaptoethanol treatment of the antibody revealed that it was of the IgG class.

- 1995 USE OF SARCOMA 180 TO PREPARE HEMAGGLUTININATING AND COMPLEMENT-FIXING ANTIGENS FOR VIRUSES IN ADULT MICE. (E.) Mettler, N. E. (Yale U. Sch. Med., New Haven, Conn.), J. Casals, D. H. Clarke, W. G. Downs and R. E. Shope. *Proc Soc Exp Biol Med* 136(4):1355-1359, 1971.

Mice of both sexes (Charles River CD (R)-1), 4-7 wk old, were inoculated i.p. with 0.2 ml of fresh sarcoma 180 ascitic fluid followed 7-9 days later, after the appearance of abdominal swelling, with i.p. injections of different viruses. Two days after viral inoculation, eastern equine, Mayaro, Sindbis, Una and St. Louis encephalitis viruses produced ascitic fluid hemagglutinins with titers of 1:32 or higher, with highest titers appearing on days 3 or 4, which were shown to be inhibited by the homologous immune fluids. With the remaining 10 viruses tested, ascitic fluids were either negative or, in the case of Hazara, Uukuniemi, and Marituba, gave such low hemagglutinin titers that further characterization was not carried out. Ten of the viruses tested produced satisfactory ascitic fluid complement fixation antigen and comparison of reactivity antigens from mouse brain and liver revealed no marked differences. Regression of the sarcomatous process was observed irregularly in mice inoculated with some of the arboviruses studied. Satisfactory antigens were obtained for arboviruses of groups A, B, C, Phlebotomus fever, Simbu, Uukuniemi, and Congo.

- 1996 STIMULATION OF AUTOCHTHONOUS LYMPHOCYTES BY CELLS FROM NORMAL AND LEUKAEMIC LINES. (E.) Knight, S. C. (New York U. Med. Ctr., New York), G. E. Moore and B. D. Clarkson. *Nature* 229 (6):185-187, 1971.

Lymphoblastoid cell lines derived from 2 leukemic patients were incubated with irradiated autochthonous and allogeneic cells (6000 rads) or with cell lines derived from normal subjects and from a patient with reticulum cell sarcoma. Stimulation of the cells was measured by uptake of tritiated thymidine. Irradiated leukemic cells stimulated both autochthonous cells and normal allogeneic cells to a similar degree. The reticulum cell sarcoma cell line did not stimulate cells from either of the 2 leukemic patients. Both autochthonous and allogeneic irradiated lympho-

blastoid cells stimulated freshly isolated lymphocytes from normal subjects; in 3 of 4 experiments, the stimulation by autochthonous cells was lower than that observed with cells from an allogeneic source. Irradiated autologous lymphoblastoid cells derived from both normal and leukemic individuals stimulated freshly isolated autochthonous cells, suggesting that the factor responsible was not a specific leukemic antigen.

- 1997 INHIBITION BY PHYTOHEMAGGLUTININ OF DNA SYNTHESIS IN CULTURED MOUSE LYMPHOMAS. (E.) Dent, P. B. (Dept. Pediat., McMaster U., Hamilton, Ontario, Canada). *J Nat Cancer Inst* 46(4):763-773, 1971.

When normal mouse spleen cells were exposed to phytohemagglutinin (PHA) in dilutions of from 1:10-1:500, DNA synthesis was stimulated 10- to 100-fold; addition of PHA to cultures of transplantable murine ascites lymphoma induced by Gross virus decreased DNA synthesis. Both stimulation and inhibition of DNA synthesis by PHA were directly correlated with increasing concentrations of the mitogen. Pokeweed mitogen (PWM) rarely inhibited DNA synthesis in the lymphoma cells, and often caused a 2- to 5-fold increase in DNA synthesis in the lymphoma cells. However, PWM did inhibit DNA synthesis in mouse myeloma cells. PHA produced slight increases in RNA synthesis in normal spleen cells, and less pronounced increases in lymphoma cells. It was found that high concentrations of PHA reduced the number of viable cells in both normal and lymphomatous cells, but the lower concentrations had no evident cytotoxicity. PHA-induced inhibition of DNA synthesis in lymphoma cells was reversible; removal of PHA from cultures allowed DNA synthesis in the cells to begin to recover. It was thought that neoplastic cells may have an increased density of mitogen receptor sites on their surfaces.

- 1998 PHYTOHEMAGGLUTININ (PHA)-INDUCED TRANSFORMATION OF LYMPHOCYTES FROM PATIENTS WITH CANCER. (E.) Sutherland, R. M. (London Clinic, Ontario, Canada), W. R. Inch and J. A. McCredie. *Cancer* 27(3):574-578, 1971.

Lymphocytes from 71 patients with cancer, 9 patients hospitalized for surgical procedures but without cancer, and 24 healthy subjects were stimulated with phytohemagglutinin (PHA) in the presence of ³H-thymidine and examined for morphological transformation and rate of nucleic acid synthesis. Cancer patients consisted of patients with lymphoma, leukemia, cancer of the breast and cervix, lung cancer and other cancers. No difference in morphological transformation of lymphocytes stimulated with PHA was noted among patients of different ages. Nucleic acid synthesis in PHA-stimulated cells declined as the age of the patient donating the cells advanced; DNA synthesis in cells from 60-yr-old patients was reduced by more than 50% of the rate of DNA synthesis in cells from 1-yr-old patients, and RNA synthesis was similarly, though not

as markedly, reduced. Morphological transformation of lymphocytes from untreated patients with acute leukemia did not differ significantly from that in the controls. Transformation was significantly reduced in untreated patients with chronic leukemia, and DNA synthesis was slightly reduced in patients with acute leukemia in all stages of the disease. Morphological transformation of lymphocytes from Hodgkin's disease patients in all stages was 75% of control values. Morphological transformation and nucleic acid synthesis were not altered in lymphocytes from untreated patients with carcinoma of the female reproductive system, lung and other cancers.

1999 SUPPRESSION OF CELL-MEDIATED IMMUNITY THROUGH IMMUNE SPLEEN CELLS AGAINST EHR-
LICH ASCITES TUMOR. (E.) Okubo, S. (Nagoya U. Sch. Med., Japan). *Nagoya J Med Sci* 33(4):329-340, 1971.

Twenty test mice and 20 control 60-day-old SMA mice received i.p. injections of 0.2 ml of either immune or nonimmune spleen cell suspension, resp. Seven days later, all animals were challenged s.c. with viable Ehrlich ascites cells. Eleven of 20 mice receiving immune spleen cells 7 days prior to tumor challenge showed progressive growth of the resulting tumor, whereas only 1 of 20 mice receiving nonimmune spleen cells showed progressive growth. Seven of 20 mice in the test group showed tumor growth within a definite period followed by regression, while 19 mice in the control group showed regression after limited growth; regression in the former was slightly retarded in comparison to the latter. Two mice in the test group failed to develop a tumor while none in the control group were without a tumor. In 10 control and 10 test mice, response to tumor formation following injection of viable tumor cells into the foot pads showed that smaller tumors formed in all immunized animals compared to the control group. Mixed tumor and immune or nonimmune spleen cells caused death of all control animals while only 2 of 10 immunized mice succumbed. Serum obtained from mice given immune spleen cells 24 hr previously enhanced the s.c. growth of Ehrlich ascites tumor, whereas serum obtained from mice that had received immune spleen cells 7 days before bleeding did not enhance tumor growth. Tumor enhancement may represent a mechanism by which autochthonous tumors possessing tumor-specific antigens may grow progressively to the death of the hosts.

2000 ANTIGENICITY OF OVARIAN AND CERVICAL MALIGNANCIES WITH A VIEW TOWARD POSSIBLE IMMUNO-
DIAGNOSIS. (E.) Levi, M. M. (Harlem Hosp. Ctr., New York, N.Y.). *Amer J Obstet Gynec* 109(5):689-698, 1971.

Rabbits were injected with tissue culture extracts from ovarian papillary cystadenocarcinoma and cervical squamous cell carcinoma. Ouchterlony double diffusion tests indicated that the antibodies produced were specific and did not cross-react with a variety of other normal and malignant tissues. Iso-

lation of the corresponding antigenic components in tumor tissue was accomplished through Sephadex gel filtration. Tumor tissue was more prevalent than normal tissue in Fraction VI and it is believed that Fraction I contained the antigenic site for the cervical tumor. Further, the antigenic components of the tumors were localized in a high molecular wt fraction. On acrylamide gel electrophoresis, it appeared that the papillary serous cystadenocarcinoma Fractions I and III were low in protein compared to normal human serum. Some evidence exists for believing that the antigens are specific. Immunologic comparison of equivalent fractions eluted from Sephadex gels showed antigenic nonidentity of the fractions derived from normal tissues with those from tumor tissues. Indications are that reproducible and reliable immunotesting procedures can be designed.

2001 DECREASING IMMUNE COMPETENCE AND DEVELOPMENT OF RETICULUM CELL SARCOMAS IN LYMPHATIC TISSUE OF AGED MICE. (E.) Hanna, M. G., Jr. (Oak Ridge Natl. Lab., Tenn.), P. Nettesheim and M. J. Snodgrass. *J Nat Cancer Inst* 46(4):809-824, 1971.

The antigen-trapping capacity of spleen germinal centers in 3 age groups of (C57BL/6 x C3H/An)F₁ (B6C3F₁) mice was studied in relation to the development of reticulum cell sarcoma and the reduction of immunity to test antigen by means of autoradiography. Antigen clearance occurred in the serum of 13-wk-old mice between days 3 and 10 after antigen injection with no comparable clearance occurring in 1.5 and 2.5-yr-old animals. However, clearance was greater in the 1.5-yr-old group than in the 2.5-yr-old animals with a 3-fold decrease in antigen between days 7 and 10 occurring in the first group; in all 3 groups, the relative rates of clearance in the spleen corresponded to those measured in the serum with a marked reduction in the young-adult mice between days 7 and 14. In the young-adult mice at 1 hr after injection with a single dose of ¹²⁵I-human gamma-globulin, label in the spleen was preferentially in the marginal zone of the lymphatic nodules and in active germinal centers or in the cortical lymphoid follicular areas. At 24 hr, the germinal centers were still heavily labeled, and label was concentrated in follicular areas lacking active germinal centers with label decreasing in other areas; in the 18-month-old mice, both the concentration of label per follicle and the total number of labeled follicles were markedly decreased and in the 2.5-yr-old mice, occurrence of germinal centers and/or antigen localization was extremely rare. A 15% increase in non-lymphatic neoplasms in 2.5-yr-old animals with reticulum cell sarcoma was observed in stages 2, 3 or 4 compared to normal, aged animals or to those categorized in stage 1 of the disease. It is not unreasonable to consider that a decrease in immune capacity of the spleen might contribute to the increased frequency of nonlymphatic tissue tumors in these animals.

2002 STUDIES OF CARCINO-FETAL PROTEINS: PHYSICAL AND CHEMICAL PROPERTIES OF HUMAN α -FETOPROTEIN. (E.) Ruoslahti, E. (Dept.

Serol. Bacteriol., U. Helsinki, Finland) and M. Seppälä. *Int J Cancer* 7(2): 218-225, 1971.

The relationship between human α -fetoprotein from serum of human fetuses, fetoproteins from other animals and other human serum proteins was investigated by means of gel electrophoresis and various chemical analyses. The reactive protein in fetal serum to anti- α -fetoprotein was located in the α -fetoprotein band in polyacrylamide gel electrophoresis, which upon purification gave 2 distinct bands with molecular wt of 140,000 and 70,000, resp., and differed from that reported for bovine fetuin at 48,800. Carbohydrate analysis revealed 24.5% contained in fetuin compared to 4.3% in α -fetoprotein. The molecular wt of α -fetoprotein is close to that of albumin and the serum concentrations seem to be inversely related.

2003 IMMUNOFLUORESCENT STUDY OF ALPHA-FOETOPROTEIN (α fp) IN LIVER AND LIVER TUMOURS: I. TECHNIQUE OF α fp LOCALIZATION IN TISSUE SECTIONS. (E.) Engelhardt, N. V. (Gamaleya Inst. Epidem. Microbiol., Moscow, U.S.S.R.), A. I. Goussev, L. Ja. Shipova and G. I. Abelev. *Int J Cancer* 7(2): 198-206, 1971.

Techniques of α -fp detection in normal embryonic liver and human and animal carcinomatous tissue, preparation of purified anti- α -fp antibodies and differentiation of structures containing the protein with those passively incorporating it are described. Paraffin sections of tissues fixed with ethanol and acetic acid revealed a better distribution of the protein than cryostat sections. Dilutions of anti- α -fp h and m antibodies obtained by glutaraldehyde immunosorbent techniques were chosen on the basis of the one giving sufficiently bright reaction with most contrast on sections of human fetal liver. Differentiation of α -fp localization due to uptake rather than production was based on the presence of the protein without the presence of the γ -globulin factor. It is believed that the cellular sites of synthesis of α -fp in embryonal liver are the parenchymal cells and the tumor cells themselves in carcinoma tissue.

2004 IMMUNOFLUORESCENT STUDY OF ALPHA-FOETOPROTEIN (α fp) IN LIVER AND LIVER TUMOURS: II. LOCALIZATION OF α fp IN THE TISSUES OF PATIENTS WITH PRIMARY LIVER CANCER (PLC). (E.) Goussev, A. I. (N. F. Gamaleya Inst. Epidem. Microbiol., Moscow, USSR), N. V. Engelhardt, R. Masseyeff, R. Camain and B. Basteris. *Int J Cancer* 7(2):207-217, 1971.

Sites of specific α fp localization in the tissues of patients with primary liver cancer were studied by immunofluorescent techniques. The concentration of α fp in tumor tissue was considerably less than in blood and comparable to levels found in extracts of tissues from liver, kidney, spleen, lung and pancreas. Two of 7 α fp-positive primary liver cancer cases showed low concentration in blood serum, and antigen was not detected in

tissue specimens by immunofluorescence techniques; in 3 cases the protein was present in liver parenchyma cells simultaneously with γ -globulin antibodies. The antigen was observed in tumor tissue by immunofluorescence in cases of α fp-positive hepatocellular carcinoma. When the concentration in blood serum was 1:64 or more, the tumor sections observed contained both the protein and γ -globulin, supporting the assumption that the site of synthesis was the tumor itself.

2005 SYNTHESIS, ASSEMBLY AND SECRETION OF GAMMA GLOBULIN BY MOUSE MYELOMA CELLS: II. ASSEMBLY OF IgG_{2b} IMMUNOGLOBULIN BY MPC 11 TUMOR AND CULTURE CELLS. (E.) Laskov, R. (Hebrew U. Haddasah Med. Sch., Jerusalem, Israel), R. Lanzerotti and M. D. Scharff. *J Molec Biol* 56(2):327-339, 1971.

Steps in the assembly of IgG_{2b} immunoglobulin after the release of heavy and light chains were studied by pulse-chase experiments with ¹⁴C-labeled valine, threonine and leucine in MPC 11 myeloma cells. The presence of a constant amount of immunologically precipitable material and constant ratio of labeled heavy and light chains between 2-20 min after the chase indicated that no selective degradation occurred. In the first 20 min after the chase, free heavy chains (H), light chains (L), half molecules (HL) and heavy chain dimers (H₂) were the main precursors of the fully assembled IgG (H₂L₂) molecule. A decreased but significant amount (50% of control) of label was incorporated into H₂L₂ in the presence of cycloheximide, indicating that interchain disulfide bond formation occurs after release of the nascent chains from the ribosome. Many half molecules were produced by the tumor cell, but they were not assembled into H₂L₂ and were secreted quantitatively as such or as higher polymers into the medium; the decrease in L, H, H₂ and H₂L accounted for 90% of the increases in fully assembled H₂L₂ and HL. This block in assembly may be due to the presence of a large excess of light chains rather than to a structural defect in the polypeptide chains.

2006 SPECIFICITY AND STRUCTURE OF THE MYELOMA PROTEIN PRODUCED BY MOUSE PLASMACYTOMA MOPC-460. (E.) Jaffe, B. M. (Washington U. Sch. Med., St. Louis, Mo.), E. S. Simms and H. N. Eisen. *Biochemistry* 10(9):1693-1699, 1971.

Balb/c anN mice in which mouse plasmacytomas were induced by serial s.c. transplantation at 3 wk intervals were exsanguinated by cardiac puncture; sera from several transplant generations were pooled and used for isolation and identification of protein MOPC-460. A final yield of purified immunoabsorbed protein 7S amounted to 2.8 mg/ml of serum or 3.95 mg/ml of serum (with an alternate method of determination). The 7S monomer was calculated to have a molecular wt of 150,000 and appeared to consist of 2 light and 2 heavy chains (the light and heavy chains were calculated to be 23,000 and 55,700, resp). In determining ligand binding, MOPC 460 appeared to have a 10-fold greater affinity for dinitronaphthol than for ϵ -DNP-L-lysine.

- 007 ELECTRON MICROSCOPY OF HUMAN AND MOUSE MYELOMA SERUM IgA. (E.) Dourmashkin, R. R. (Natl. Inst. Med. Res., London, England), G. Virella and R. M. E. Parkhouse. *J Molec Biol* 56(1):207-208, 1971.

Immunoglobulin A (IgA) fractionated and purified from the serum of a patient with a secreting myeloma and mouse myeloma IgA, MOPC 315, were examined by electron microscopy. A "double Y" appearance was photographed in most molecules from both specimens; the branching arms appeared more distinct in the mouse fraction compared to the human fraction and was suggestive of a structure consistent with two 7S units, each made up of 2 heavy and 2 light chains, joined together at or near the C-terminal of the heavy chains.

- 008 ELECTRON MICROSCOPY OF COMPLEXES BETWEEN IgA (MOPC 315) AND A BIFUNCTIONAL HAPTEN. (E.) Green, N. M. (Natl. Inst. Med. Res., London, England), R. R. Dourmashkin and R. M. E. Parkhouse. *Molec Biol* 56(1):203-206, 1971.

Mouse myeloma protein, immunoglobulin A (MOPC 315), was isolated as a mixture of unreduced oligomers and was titrated with a bifunctional hapten, bis(DNP-alanyl)-diaminosuccinate, and with a monofunctional hapten, ϵ -DNP-aminocaproate. The bifunctional compound was bound about 10 times as strongly as the monofunctional compound. Electron microscopy revealed the absence of Fab fragments linked to each other. A central, highly contrasted double bar, from the four ends of which extended either a short weakly contrasted projection or a longer arm terminating in a fork, was the most striking feature. Four terminal half molecules, lacking in polymers formed from reduced preparations, appeared to form a tetramer by side-by-side aggregation of two cyclic dimers of the repeating unit or a tetramer in which all four molecules are linked by a hapten to give a cyclic structure. Further experiments should help to clarify the nature of these complexes.

- 009 IMMUNOGLOBULIN SYNTHESIS AND SECRETION: VI. SYNTHESIS AND INTRACELLULAR TRANSPORT OF IMMUNOGLOBULIN IN NONSECRETORY LYMPHOMA CELLS. (E.) Sherr, C. J. (New York U. Sch. Med., New York, N. Y.) and J. W. Uhr. *J Exp Med* 133(4):901-920, 1971.

An established line of Burkitt lymphoma cells (Daudi) synthesizing immunoglobulin M but lacking a well defined endoplasmic reticulum (cultured in fetal calf serum) and an established line of mouse myeloma cells that secrete immunoglobulin G1 (cultured in horse serum) were labeled with ^3H -leucine or ^3H -sugars. The incorporation of labeled-leucine in the mouse myeloma cells was linear throughout the labeling period with a pattern no different from that of other immunoglobulin-secreting cells. However, label incorporation intracellularly was linear for approximately 60 min, followed by a short lag phase when label was secreted into the medium and a "steady state" was reached in 60-120 min. In contrast, Daudi cells incorporated the labeled-leucine into

intracellular immunoglobulin with no evidence of secretion into the medium even after a 6 hr period. The percentage of newly synthesized protein was 1-2% as compared to 20% in the mouse myeloma cells. Daudi cells incorporated approximately 3 times the radioactivity into the postmicrosomal supernatant than other cell types. Treatment with specific antisera to immunoglobulin showed that 3.3% of the incorporated radioactivity occurred in the bound polyribosomes and 0.4% in the free polyribosomes that precipitated as immunoglobulin; in the postribosomal supernatant 2.5% of the radioactivity was found in immunoglobulin. Label incorporation into total acid-precipitable molecules in the microsomes and cell sap was virtually linear throughout the labeling period; most of the label was found in the microsomes and after 90 min was contained in peaks having the mobility of heavy and light chains. Galactose and fucose addition occurred within the Golgi complex. The possibility that the carbohydrate moiety is incomplete or abnormal cannot be excluded.

- 2010 HAPTOGLOBIN (Hp) LEVEL OF BLOOD SERUM IN LEUKAEMIC PATIENTS. (E.) Gurda, M. (Med. Acad., Cracow, Poland). *Folia Haemat* 95(1):37-41, 1971.

Blood serum haptoglobin levels were determined for 175 patients with acute, chronic myelogenous or chronic lymphocytic leukemia. Normal haptoglobin values were 98-120 mg% (arithmetic mean); all leukemic patients had haptoglobin values significantly elevated over normal. Values for acute, chronic myelogenous and chronic lymphatic leukemia were 216.49, 191.67, and 200.00 mg%, respectively. The differences in haptoglobin values among the 3 types of leukemia were not statistically significant, and no significant differences could be found between haptoglobin values of patients of differing sex and age.

- 2011 IMMUNOGLOBULIN LEVELS IN CHRONIC LYMPHOCYTIC LEUKAEMIA. (E.) Scamps, R. A. (Repatriation Gen. Hosp., Concord, Australia), A. M. Streeter and B. J. O'Neill. *Med J Aust* 1(10):535-536, 1971.

Serum immunoglobulin levels were determined by the radial diffusion technique for 43 hospital patients with chronic lymphocytic leukemia and for 42 normal subjects. Estimation of the total serum gamma-globulin levels by standard paper electrophoresis showed a reduction in total gamma-globulin in only 37% of leukemia patients. Serum IgG levels of leukemia patients, however, showed a mean value of 795 mg/ml, significantly reduced from the normal mean of 1,205 mg/ml. The serum IgA levels in leukemia patients showed a mean of 140 mg/ml compared to the mean for normal of 215 mg/ml. The most marked reduction in leukemia patients was in IgM; leukemic patients showed mean values of 30 mg/ml, and normals showed means of 140 mg/ml. The reductions in serum immunoglobulin levels showed no obvious correlation with any feature of the disease or clinical treatment.

- 2012 TRANSPLANTATION OF BOVINE LYMPHOSARCOMA.
(E.) Donawick, W. J. (Sch. Vet. Med., U. Pennsylvania, Kennett Square), C. Johnstone, J. G. Martens, D. C. Dodd, J. E. Martin and R. R. Marshak. *Bibl Haemat* 36:493-499, 1970.

Calves were given injections of antilymphocyte serum (ALS) in amounts of 2 ml/kg s.c. every second day, beginning 13 days prior to the administration of cell suspensions of lymphosarcomas prepared from adult cows. Lymphosarcoma cells were transplanted to the vicinity of the prefemoral lymph nodes of the calves. In 10 of 14 primary passage attempts, progressively growing lymphosarcomas appeared in ALS-treated calves; 3 of 6 calves developed tumors in the first serial passage. Subsequent attempts to pass the tumor serially were fruitless. In calves in which ALS treatment was suspended 37 days after lymphosarcoma transplant because there was no evidence that the transplant had taken, enlarged peripheral lymph nodes and leukemic peripheral blood counts were observed after 2 wk. Lymphosarcoma developing in 4 calves was generalized; in other calves, lymphosarcomas had spread from the site of inoculation to the iliac lymph nodes. No tumors developed within 100 days after challenge with lymphosarcoma cells in untreated control calves or in calves given normal horse serum.

- 2013 IMMUNOFLUORESCENT STUDIES IN LYMPH NODES FROM CATTLE AFFECTED WITH BOVINE LEUKOSIS.
(E.) Trainin, Z. (Kimron Vetr. Inst., Bet Dagan, Israel) and U. Klopfer. *Bibl Haemat* 36:500-503, 1970.

Lymph nodes and spleens of leukotic cattle were examined by direct immunofluorescence staining with conjugated rabbit anti IgM bovine serum and conjugated rabbit anti-IgG bovine serum to determine whether these 2 proteins were present in spleens and lymph nodes of animals which lacked IgM in their blood. In neoplastic lymph nodes of cattle whose blood lacked IgM, and in those of 1 cow having IgM in the blood, no cells containing IgM were found. Normal lymph nodes and spleens of blood IgM-negative cows contained IgG but not IgM. There appears to be a connection between the disappearance of IgM from the blood of leukotic cattle and the absence of IgM from spleen and lymph nodes.

- 2014 ANTIGENICITY OF HUMAN CHORIOCARCINOMA.
(E.) Srivannaboon, S. (U. Michigan Med. Ctr., Ann Arbor). *Int J Fertil* 16(1):36-41, 1971.

Rabbits immunized in the foot pads with 1 ml of choriocarcinoma tumor cell homogenate emulsified in equal volumes of Freund's incomplete adjuvant were challenged 4 wk post-immunization on 3 consecutive days with i.v. injections of 0.4 ml of the tumor cell suspensions without adjuvant. Pooled rabbit antiserum was absorbed with normal hamster serum and placenta, normal human kidney and placenta, and human chorionic gonadotropin. Results of immunoelectrophoresis patterns obtained with unabsorbed and absorbed antisera showed a degree of cross-reactivity

between hamster placenta and human choriocarcinoma. A significant decrease in cell viability was seen following incubation of cells cultured *in vitro* and treated with the rabbit antiserum to human choriocarcinoma.

- 2015 CELLULAR IMMUNITY TO NEPHROBLASTOMA. (E.) Diehl, V. (Karolinska Hosp., Stockholm, Sweden), B. Jereb, J. Stjernswärd, C. O'Toole and L. Ahström. *Int J Cancer* 7(2):277-284, 1971.

Tumor-related cell-bound immunity to autochthonous and allogeneic nephroblastoma tumor cells was studied in human lymphocytes by means of micro-plate assay. Cytotoxic reduction by lymphocytes from healthy subjects and surgical patients was 27.8% for the tumor and 21.8% for normal tissue with corresponding figures for lymphocytes from patients with tumors other than nephroblastoma showing no significant difference at 32.3% and 48.2%, resp. In 10 out of 24 nephroblastomas, cytotoxic reduction by lymphocytes was significantly increased at $P < 0.01$, < 0.05 , and < 0.001 , and in 11 out of 26 micro-plate tests the reduction of tumor cells by test lymphocytes was significantly higher than that of control lymphocytes. No significant difference in the reactivity of 3 tumor tissues to cytotoxic lymphocytes was observed and in 26 micro-plate tests the specific cytotoxicity ranged between 22.3% and 35.8% when the allogeneic control cytotoxicity was taken as zero point. Lymphocytes from only 2 out of 8 patients with generalized disease had a stronger reaction on tumor tissue than those of control subjects, while lymphocytes from 8 out of 16 patients without dissemination of the disease reacted more strongly than those of control individuals. It is not known whether the present findings reflect true variation in tumor-related cytotoxic reactivity or whether the variation is due to a general decrease in immunologic reactivity with increasing tumor burden.

- 2016 HOST IMMUNE RESPONSE TO A COMMON CELL-SURFACE ANTIGEN IN HUMAN SARCOMAS: DETECTION BY CYTOTOXIC TESTS. (E.) Wood, W. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and D. L. Morton. *New Eng J Med* 284(11):569-572, 1971.

Host immune response to cell-surface antigen in human sarcomas was studied by means of microcytotoxicity testing. Cytotoxicity to an osteosarcoma cell line was revealed in 58 of 83 serum samples from patients with different histologic types of sarcomas. Immunization of sarcoma patients with autochthonous irradiated sarcoma cells induced an increase in titer of cytotoxic antibody. These results suggest the possibility of favorably altering the immune response of a sarcoma patient to his tumor.

2017 ANTIGENS OF HUMAN WART TISSUE. (E.)
 Pass, F. (Albert Einstein Coll. Med.,
 Bronx, N.Y.), R. Janis and D. M. Marcus.
Invest Derm 56(4):305-310, 1971.

Adult male rabbits were immunized with 10 mg inocu-
 lations of a homogenate prepared from human wart
 tissue, and sera were collected for immunological
 study. On indirect immunofluorescence tests,
 tissue from 5 human warts showed areas of nuclear
 and cell surface fluorescence; fluorescence was
 usually most conspicuous in the stratum granulosum.
 It was not possible to determine whether the cell
 surface fluorescence was due to the cell membrane
 or intercellular antigens. Rabbit antiserum did
 not produce a fluorescent reaction when reacted
 with normal human skin. A single band of
 precipitation was seen when the rabbit antisera
 were reacted with an aqueous extract of wart
 tissue in agarose gel diffusion. The rabbit
 antiserum showed nuclear and cell surface fluores-
 cence when reacted with keratoacanthomas and
 squamous cell carcinomas. No fluorescence was
 seen when antiserum was reacted with basal cell
 carcinoma tissue. Immunofluorescence and gel
 diffusion reactions were inhibited by absorption
 of rabbit antisera with large quantities of
 normal skin or tumor homogenates; however, the
 reactions were not inhibited by absorbing the
 antiserum with wart virus.

2018 IMMUNOLOGICAL STUDIES WITH HUMAN GLIOMAS.
 (E.) Mahaley, M.S., Jr. (Duke U. Med.
 Ctr., Durham, N.C.). *J Neurosurg* 34(3):458-459,
 1971.

The antigenic potential of human gliomas and the
 feasibility of producing heterologous antiglioma
 "carrier" antibodies capable of preferential glioma
 localization *in vivo* were studied utilizing fresh
 human glioma tissue homogenate for immunization of
 rabbits. In patients receiving radioantibody in the
 form of heterologous antiglioma globulin (125 I)
 infusion prior to a second operation, external brain
 scans revealed localization of the antibody within
 the area of the recurrent glioma. Upon direct
 inspection, localization within tumor tissue as
 compared with normal brain tissue was found in the
 majority of cases. To date, no proof of specific
 glioma antigens or specific antiglioma antibody
 production has been established.

2019 TONSILLECTOMY AND HODGKIN'S DISEASE: THE
 LYMPHOID TISSUE BARRIER. (E.) Vianna, N. J.
 New York St. Dept. Hlth., Albany, N. Y.), P. Greenwald
 and J. N. P. Davies. *Lancet* 1(7696):431-432, 1971.

Interviews were conducted with 109 patients with Hodg-
 kin's disease and 109 controls to determine whether
 the former group included an unusually large number of
 subjects who had undergone tonsillectomy. It was
 found that 67 Hodgkin's disease patients and 43 con-
 trols had undergone tonsillectomies. The estimated
 relative risk of developing Hodgkin's disease among

those with a history of prior tonsillectomy was 2.9
 times higher than that for those who had never been
 tonsillectomized. It was hypothesized that surgical
 removal of active lymphoid tissue in some way facili-
 tates the onset of Hodgkin's disease, perhaps by re-
 moving a protective barrier.

- 2024 ENZYME HISTOCHEMISTRY AND AUTORADIOGRAPHIC STUDIES DURING DEVELOPMENT OF URINARY BLADDER TUMORS OF THE RAT. (Ger.) Kunze, E. (Path. Inst. U. Munich, Germany) and A. Schauer. *Z Krebsforsch* 75(2):146-160, 1971.

Hyperplasia of the urinary bladder mucosa followed the administration of dibutyl nitrosamine (20 mg/kg/day in drinking water) to female Wistar rats. The hyperplastic mucosa showed zero alkaline phosphatase activity, diminished NADPH-diaphorase and elevated succinic dehydrogenase. The hyperplastic areas developed 16 papillomas and 2 carcinomas, and these lesions also showed no alkaline phosphatase activity. The papillomas retained NADPH-diaphorase and succinic dehydrogenase at normal levels except in certain regions where the former enzyme was diminished and the latter was increased. In areas of zero alkaline phosphatase the ^3H -thymidine labeling index/100 cells had increased 41-fold over normal levels; the increase in the ^3H -thymidine labeling index was 105-fold in papillomas. Papillomas showed a 150% rise and enzyme-defective zones a 190% rise in grain density/surface unit values.

- 2025 TRANSFER RIBONUCLEIC ACIDS IN RAT LIVER AND MORRIS 5123 MINIMAL DEVIATION HEPATOMA. (E.) Gonano, F. (Inst. Gen. Path., U. Modena, Italy), V. P. Chiarugi, G. Pirro and M. Marini. *Biochemistry* 10(5):900-908, 1971.

Alterations in the chromatographic patterns of transfer ribonucleic acids obtained from rat liver and so-called "minimal deviation hepatoma" Morris 5123 were compared by reverse phase chromatography. Seventeen out of 20 amino acids showed the same profile for both rat liver and Morris 5123 hepatoma tRNA. Asparaginyl-tRNA was eluted from the Morris hepatoma at slightly higher salt concentrations in relatively different proportions; glutamyl-tRNA showed one peak of acceptor activity in the hepatoma compared to two in rat liver, whereas glutaminyl-tRNA showed a reverse profile. Phenylalanyl-tRNA differed also between the two tissues with respect to acceptor activity peaks and elution fractions. However, no significant differences were observed among the phenylalanyl-tRNAs from liver, Morris hepatoma and *E. coli* in their capacity to synthesize polyphenylalanine in response to polynucleotide template. In the tumor cell, the appearance of a new tRNA or the disappearance of a tRNA could influence the translation of some pre-existing mRNA into which amino acids have to be inserted.

- 2026 THE "STADE EPHELIDE" OF PRECANCEROUS MELANOSIS: A COMPARATIVE, CLINICAL, HISTOPATHOLOGICAL AND ELECTRON MICROSCOPICAL STUDY. (Ger.) Anton-Lamprecht, U. (U. Clin. Heidelberg, Germany), U. W. Schnyder and W. Tilgen. *Arch Derm Forsch* 240(1):61-78, 1971.

A case of "stade ephelide" arising in a 60-yr-old man presented the clinical features of a growing hyper-

pigmented facial freckle; histopathological evaluation of the freckle showed that the hyperpigmentation was confined to the basal and suprabasal cells of the epidermis. Under the electron microscope, the freckle - thought to be an early stage of cancerous melanosis - showed abundant malignant melanocytes in the basal cell layer. These melanocytes showed increased synthetic activity, and their melanin granules were similar to those seen in later stages of precancerous melanosis.

- 2027 PROLIFERATIVE CHANGES OF THE EPITHELIUM OF THE FALLOPIAN TUBE IN PATIENTS WITH ENDOMETRIAL CARCINOMA. (Ger.) Dallenbach-Hellweg, G. (Mannheim Clin., U. Heidelberg, Germany) and W. Rom. *Arch Gynaek* 209(4):396-410, 1971.

Non-invasive epithelial proliferation *in situ* was found in the fallopian tubes of 58 post-menopausal women with carcinoma of the endometrium. Fallopian tube epithelium also showed stratification, papillae and small alveolar spaces. The cytoplasm of the epithelial cells was rich in RNA, and their nuclei were large, pleomorphic, and rich in DNA. Therapy with estrogen had varying effects on fallopian tube hyperplasia and endometrial carcinoma. Patients aged from 60-70-yr-old showed the most extensive epithelial proliferation in their fallopian tubes. Estrogen stimulation was thought to be the cause of both the endometrial cancer and the hyperplasia of the fallopian tubes. In some cases, tubal hyperplasia had its onset prior to the onset of endometrial carcinoma, and in other cases the 2 conditions were initiated simultaneously.

- 2028 DARK CELLS IN THE EPITHELIAL TUMORS OF THE URINARY BLADDER. (Rus.) Romanenko, A. M. (Sci. Res. Inst. Urology, Kiev, U.S.S.R.). *Arkh Patol* 33(3):33-37, 1971.

Histological and histochemical investigations of the dark cells in 100 human bladder epithelial tumors (14 transitional cell papillomas, 28 well-differentiated, 32 moderately differentiated and 26 anaplastic tumors) revealed that the amount of dark cells increased with the progression of dedifferentiation. The polymorphism of the dark cells increased with the intensification of atypia of the light cells and was maximal with anaplastic tumors. An accumulation of nucleic acids, SH-groups and S-S bridges and a decrease in acid and neutral mucopolysaccharides was noticed with the progression of atypia. The histochemical features of the dark cells indicated that they were the most active epithelial elements within the tumor tissue and the rate of their occurrence appeared to correlate with increasing malignancy.

- 2029 BENIGN MAMMARY TUMORS AND CANCER DEVELOPMENT. (Ger.) Bussmann, J. F. (Mannheim Clin. U. Heidelberg, Germany), K. R. Loewe and H. S. Fürstenberg. *Bruns Beitr Klin Chir* 218(5):393-402, 1971.

Four hundred mammary benign tumors were classified as 205 chronic fibrosa cystica, 122 fibromatosis, and 73 fibroadenoma. The incidence of the development of malignancy from benign tumors was evaluated and compared to the normal population. Such development was often related to an increase in epithelial cell proliferation which was particularly marked in the cases of chronic fibrosa cystica, but was also found in the other types examined. Statistical evaluation was difficult since other factors, changes in the breast at the time of the menopause and malignancy attributable to ovulation inhibitors, often interfered with judgment of carcinogenesis. In one case where a mastectomy was not performed in the face of finding increased epithelial cell proliferation and atypical nuclei and which was diagnosed as fibrosa cystica, the patient developed a carcinoma in 10 yr; but in 2 patients with fibromatosis and increased epithelial cell proliferation and in whom mastectomy was not performed, no carcinoma had developed 8-10 yr later.

- 2030 PRECANCEROUS ALTERATIONS OF THE HUMAN THYROID. (Rus.) Zaridze, D. G. (Inst. Exp. and Clin. Oncol. Acad. Med. Sci. Moscow, U.S.S.R.) and N. T. Raykhlin. *Arkhl Patol* 33(3):16-22, 1971.

The pathogenic relationship between the nodular goiter, thyroid adenoma and thyroid cancer was investigated in preparations from 38 thyroid adenomas and 67 thyroid cancer patients. Epithelial proliferation of monomorphous cells with well-defined boundaries and oval nuclei towards the interfollicular spaces was the main feature observed in adenomas. A thickening of the follicular walls consisting of several cell layers was seen, often leading to the development of papillary structures with a well-defined connective stroma. Giant cells and a beginning of cell polymorphism with elongated and hyperchromic nuclei were seen in 7 of the adenomas and were suggestive of premalignant alterations. Adenomatous regions with considerable polymorphism of the epithelial cells surrounding the cancerous foci were observed in 32 of 67 cancer preparations.

- 2036 LYMPHOSARCOMA IN INDIAN ZEBU CATTLE. (E.) Naik, S. N. (Cancer Res. Inst., Tata Mem. Ctr., Bombay, India), R. D. Dabholkar and H. P. Randelia. *Oncology* 25(1):72-78, 1971.

The epidemiological, clinical and histopathological findings of bovine lymphosarcoma are discussed on the basis of a survey of more than 79,000 male adult Indian cattle of seven different breeds and crossbreeds in India. Only one case of lymphosarcoma was detected in a Malvi bullock of about 9-10 yr of age; a clinical picture of debilitation was seen with pale mucous membranes and symmetrically enlarged regional lymph nodes accompanied by difficulty in breathing due to enlarged pharyngeal and mediastinal lymph nodes. The lymph nodes were soft, greyish to reddish in color and bulged from the surface when cut, revealing a loss of cortico-medullary architecture with proliferative and necrotic areas; the enlarged spleen weighed 1,705 g and had an irregular border with elevated areas on the surface. The animal presented an anemic blood picture ($RBC=3.34 \times 10^6/l/cm^3$) and lymphocytosis (73%, $12,191/cm^3$) with atypical lymphocytes containing double nuclei and vacuoles in the cytoplasm and large numbers of immature lymphocytes or lymphoblasts. The liver, kidney and lungs showed no evidence of disease. The ultimate proof of an association between leukemia in domestic animals and man will depend on careful epidemiological investigations and isolation of the causative agent.

- 2037 ASSOCIATION BETWEEN RAINFALL AND ESOPHAGEAL CANCER IN CHILE. (E.) Zaldivar, R. (U. Tennessee Coll. Med., Memphis) and H. Robinson. *Beitr Path* 142(4):403-406, 1971.

A negative correlation was found between rainfall and incidence of esophageal cancer in Chile. Incidence rates for this condition in 1962-1964 were maximal (e.g., 0.8-1.3 log cases of esophageal cancer) in low-rainfall areas of the country (e.g., 0.05-0.5 log total rainfall in 1964) and minimal (e.g., 0.05-0.4 log cases) in areas of heavy rainfall (e.g., 3.0-3.6 log total rainfall). It was noted that the areas of low rainfall and high esophageal cancer incidence were areas of highly alkaline soil conditions; however, the possibility of a connection between alkalinity of soil and esophageal cancer was not explored.

- 2038 PATTERN OF MALIGNANCY IN A PLACE IN WESTERN INDIA. (E.) Kirtane, J. S. (Med. Coll. Baroda, India), B. A. Sayed and V. P. Vaishnav. *Brit J Cancer* 24(4):670-672, 1970.

The incidence of cancer of various sites in a population from Baroda, India was investigated, and it was found that of 4500 cases of malignancy, 25% involved cancer of the buccopharynx and 27.8% involved the female genital tract. Buccopharyngeal cancer affected more men than women, and accounted for 39.5% of all malignancies in men and for 4.8% of all malignancies in women. Most female genital tract cancer involved the cervix. Esophageal cancer was the most commonly

affected site in the gastrointestinal tract. Most cancers observed were epithelial in origin; sarcomas comprised only 6.2% of the observed malignancies. The high rate of buccopharyngeal cancer in men and its low rate in women may be due to the habit of chewing a mixture of tobacco and lime which is widespread among men in this area of India.

- 2039 THE EPIDEMIOLOGY OF CANINE LEUKEMIA AND LYMPHOMA. (E.) Dorn, C. R. (Sch. Vetr. Med., U. Missouri, Columbia), D. O. Taylor and R. Schneider. *Bibl Haemat* 36:403-415, 1970.

A survey of the occurrence of leukemia and lymphoma among dogs in Alameda County, California revealed that the average annual incidence rate for lymphosarcoma and reticulosarcoma for dogs (24.2 cases/1000,000 population) was higher than the rate for men (4.7 cases/100,000) and lower than the rate for cats (128.4/100,000). No evidence of spatial or temporal clustering could be found for leukemia or lymphoma in dogs, nor did the incidence of these conditions exhibit any seasonal pattern. About 89% of leukemia-lymphoma diagnoses among dogs in Alameda county were lymphosarcomas, and the incidence rate for lymphosarcomas among dogs increased with age of the dog up to 11 yr-of-age, the period of peak incidence (84.03/100,000). Male and female dogs appeared to have comparable risks for developing lymphosarcoma. Age-specific incidence rates for lymphosarcoma among dogs were lower than the rates for mastocytoma and fibrosarcoma, and higher than rates for hemangiosarcoma and osteosarcoma. Of 8 breeds of dogs examined, only the boxer had a significantly greater number of lymphosarcoma cases than expected, the risk of lymphosarcoma development among boxers being 9.5 times higher than the risk among all other dogs combined. Boston terriers were found to be at an unusually high risk for malignant mastocytoma and hemangiosarcoma. No pattern of multiple occurrence of primary malignancies was seen, although sarcomas and lymphomas were seen to occur in the same dog.

- 2040 SOME LESSONS FROM CANCER PATTERNS IN AFRICA. (E.) Burkitt, D. P. (Med. Res. Council, London, England). *Med Proc* 17(4-5):52-58, 70-74, 1971.

Incidence of cancer of various sites in various regions of Kenya and Tanzania was investigated. Esophageal cancer was more rare in western Kenya and Tanzania than in the central and eastern regions of those countries and most prevalent in the vicinity of Lake Victoria. Kaposi's sarcoma was more common in the western parts of Kenya than in the east, as was carcinoma of the penis. Malignant lesions of the breast were more common in areas where benign lesions were widespread, and cancer of the colon was associated with appendicitis, diverticular disease, and adenomatous polyps. The rarity of bronchial carcinoma in Africa seemed to be related to the fact that relatively few Africans smoke cigarettes. The inverse relationship discovered between age at first pregnancy and liability of developing breast cancer

probably accounted for the low incidence of this condition in Africa. Cancer of the penis had a high incidence in parts of Africa where male circumcision was not the rule. Burkitt's lymphoma was especially prevalent in areas in which there was a high incidence of malaria, suggesting an insect vector for Burkitt's lymphoma. The use of tin-coated metal drums for the distillation of spirits and the use of maize beverages have both been suggested as etiological factors in the development of esophageal cancer in Africa.

2041 CANCER SURVEY IN SOUTH IRAN WITH SPECIAL REFERENCE TO GASTROINTESTINAL NEOPLASMS.

(E.) Barekat, A. A. (Pahlavi U. Sch. Med., Shiraz, Iran), F. Saidi and W. Dutz. *Int J Cancer* 7(2):353-358, 1971.

A survey of 1,987 male and 1,288 female cancer cases from the Fars Province of Iran was carried out to determine the relative frequencies of cancers of various sites in that region. The predominant malignant condition among males in the Fars Province was skin cancer, accounting for 19% of cancer cases. In Iran generally, skin cancer accounted for 26% of all cancers, while in Sweden it accounted for only 5% of all cancers. Cancer of the lymphoid system was the next most frequent malignancy in the area, comprising 12.4% of cancer cases, a proportion comparable to the proportion of all of lymphoid cancer cases in Iran generally and in Sweden. Cancer of the hematopoietic system was more prevalent in the Fars Province (5.6% of all cancers) than in Iran generally (0.4% of all cases). The most common cancer among females in the Fars Province was skin cancer and the next most prominent was cervical cancer, with incidences of 15.6 and 13.5% of all cancers, resp. While the prevalence of cervical cancer was similar in the Fars Province and in Sweden, breast cancer was more frequent in Sweden. Breast cancer, the third most prominent cancer among Fars Province females, was far less prevalent in Fars than in Sweden. While the frequency of esophageal cancer was relatively high, there was a dearth of cancer of the colon in Fars Province. Twenty-five percent of all lymphomas (18.1% and 11.2% in males and females, resp.) occurred primarily in the gastrointestinal tract.

2042 ASSESSMENT OF RISK PATTERNS IN CANCER OF THE CERVIX: A COMPARISON BETWEEN GREATER BOMBAY AND WESTERN COUNTRIES. (E.) Jussawalla, D. J. (Bombay Cancer Registry, India), V. A. Deshpande and J. Standfast. *Int J Cancer* 7(2):259-268, 1971.

A survey of 503 Bombay women with cervical cancer, was found that patients with cancer of the uterine cervix appeared to have married at an earlier age than women without cervical cancer; 60% of cancer patients had married before age 15 as against 37% of healthy controls. Six percent of the cancer patients became pregnant for the first time before age 15, compared to 1.1% for women without cervical cancer; furthermore, the risk of developing cancer of the uterine cervix was found to be 14 times higher in

women who had become pregnant for the first time before age 15 than it was in nulliparous women. Risk of developing cervical cancer increased in direct proportion to the number of pregnancies and was significantly higher in women who had undergone 3 or more pregnancies than in nulliparous women. Elapsed time between pregnancies was also correlated with risk of cervical cancer; women undergoing pregnancies in quick succession had a higher risk than women spacing their pregnancies.

2043 CANCERS OF THE LUNG AND NASAL SINUSES IN NICKEL WORKERS. (E.) Doll, R. (Dept. Regius Prof. Med., U. Oxford, England), L. G. Morgan and F. E. Speizer. *Brit J Cancer* 24(4):623-630, 1970.

A survey was conducted on 845 workers in a nickel refining installation in South Wales to determine whether this population had an unusually high mortality rate from lung and nasal carcinoma. The 845 workers had been employed at the nickel plant for at least 5 yr and in all cases, their employment had commenced before 1944. Men starting employment before 1925 had a mortality from nasal cancer varying from 100-900 times that in Britain at large; in this group the expected number of nasal cancer deaths was 0.107 and the observed number was 39. No deaths from nasal sinus cancer were seen in men who started work in the nickel plant in 1925 or later, by which time the carcinogenic nickel carbonyl had been eliminated from nickel plants. The observed mortality from lung cancer in nickel workers commencing work before 1925 was 5-10 times that expected in the nation at large. Mortality from other cancers was also slightly elevated among nickel workers employed before 1925, observed and expected deaths from other neoplasms in this group being 49 and 31.5, resp. Mortality from causes other than cancer was about 20% above that predicted for all England and Wales in the pre-1925 nickel workers. It was found that susceptibility to induction of nasal cancer increased with age at first employment in the nickel plant, and that risk remained approximately constant for 15-42 yr after the carcinogen had been removed from the workers' environment. Susceptibility to induction of lung cancer, on the other hand, did not increase with age at first exposure to the nickel plant environment, and risks for lung cancer varied irregularly. The risk of lung cancer development declined after removal of the carcinogen from the environment; the earlier high mortality may have eliminated nickel workers who were heavy cigarette smokers from the study population.

2044 EPIDEMIOLOGY OF FELINE LEUKEMIA (LYMPHOSARCOMA). (E.) Brodey, R. S. (U. Pennsylvania Sch. Vetr. Med., Philadelphia), S. K. McDonough, F. L. Frye and W. D. Hardy. *Bibl Haemat* 36:333-342, 1970.

The incidence of feline lymphosarcoma (LSA) was investigated in 64 cats residing in 15 household "clusters." Thirty-eight cases of LSA were surveyed in this population. Ten of the household clusters contained 2 cats, 3 contained 3 cats, 1 contained 4 cats

and 1 contained 5 cats. The proportions of affected cats to the number of cats in the cluster ranged from 2/7 to 3/3, and the interval between deaths of cats from LSA in a single cluster ranged from 2-33 months. Most LSA lesions were multicentric; however, favored single sites were the alimentary system and the mediastinum. Only 2 of the 38 affected cats were related, suggesting that transmission of LSA among cats in a cluster was horizontal, perhaps proceeding *via* the transmission of virus in saliva. In several of the clusters, cats moved between households, a factor which appeared to be important in the transmission of LSA in these clusters.

- 2045 PREVALENCE AND INCIDENCE RATES OF CERVICAL ATYPIA: A COMPUTERIZED FILE ANALYSIS ON 148,735 PATIENTS. (E.) Bibbo, M. (Dept. Obstet. Gynec. U. Chicago, Ill.), C. M. Keebler and G. L. Wied. *J Repr Med* 6(4):184-188, 1971.

A computerized survey of 148,735 patients undergoing screening for cervical atypia over a 10-yr period showed that dysplasia was most common in women 25-29-yr-old (1,036 cases), carcinoma *in situ* was most common in women 25-29-yr-old (244 cases), and invasive carcinoma was most common in women 49-yr-old or over (111 cases). The lowest rate of prevalence of cervical dysplasia was found among women 49-yr-old or over. Prevalence rates for cervical lesions were calculated for pregnant women, currently non-pregnant women, current oral contraceptive users, current IUD users and women who used neither oral contraceptives nor IUD's prior to their first cervical examination. Current IUD users had the highest prevalence rates for cervical dysplasia among the 6 groups, and women using neither IUD's nor oral contraceptives had the lowest prevalence rates for dysplasia. Current oral contraceptive users and current IUD users had higher prevalence rates for carcinoma *in situ* than other selected groups. Women currently not pregnant and women using neither IUD's nor oral contraceptives had higher rates of invasive squamous cell carcinoma than other groups; pregnant women had the lowest rate of invasive cancer.

- 2046 EPIDEMIOLOGY OF MESOTHELIOMA ON WALCHEREN ISLAND. (E.) Stumphius, J. (Vlissingen, The Netherlands). *Brit J Indust Med* 28(1):59-66, 1971.

Of 277 shipyard workers from Walcheren Island (Netherlands) who had no history of acute or continuous exposure to asbestos dust, 160 (57.8%) showed asbestos dust bodies in sputum samples. Among workers with no exposure to asbestos dust, the percentage of positive sputum samples was 39.4%, while among those with histories of exposure to iron vapor, rust and "some" asbestos dust, percentages of positive sputum samples ranged from 70-100%. Many of the workers currently employed in occupations not exposed to asbestos dust who had asbestos bodies in their sputum had been exposed to asbestos dust 5-10 yr prior to the time of the experiment. Of 25 cases of mesothelioma recorded on Walcheren Island between 1962-1968,

22 had been employed in the shipbuilding industry at some time, and all but 3 of these workers had been exposed to asbestos dust sometime in the course of their employment in the shipyards. The incidence of mesothelioma in the shipyard population was about 100 cases/100,000 males/yr, while the incidence rate for Dutch provinces with heavy industry was 1 case/100,000 males/yr. Incidence of mesothelioma among workers in the shipyards with no asbestos exposure and among workers with "some" asbestos dust exposure were 50 and 280 cases/100,000 males/yr, resp.

- 2047 BREAST CANCER ANOMALIES. (E.) Stocks, P. (Colwyn Bay, North Wales). *Brit J Cancer* 24(4):633-643, 1970.

Death rates from breast cancer among women under 45 yr of age in England and Wales decreased between 1951-1959, then rose during 1960-1969 from 121 deaths/10⁶ population in 1959-1963 among women 25-44-yr-old to 136 deaths/10⁶ population in 1964-1967 in the same age group. Breast cancer death rates were lower in the north of England and in Wales than in southern England, with 600 deaths/10⁶ population occurring among women aged 45-64 in the Northern Counties in 1959-1963 and 783 deaths/10⁶ population occurring in the same age group in "greater London". After 1958 the excess of breast cancer deaths in southern England among women under 45-yr-old disappeared. The reasons for the increase in breast cancer death rates since 1960, and for the lower mortality in the north are unknown. An inverse relationship was seen between incidence of breast cancer and incidence of uterine cancer in northern and southern England; the breast cancer: uterine cancer death rates ratio among women in the Northern Counties aged 45-64-yr-old in 1959-1963 was 1.98 while the ratio for the same age group at the same time in greater London was 3.18. Total mortality from breast and uterine cancer combined, however, has shown little regional variation. The northern regions having low breast cancer rates were found to be regions where the consumption of liquid milk was low; high breast cancer rates (e.g., in London) were found to be correlated with high milk consumption. Similar correlations were found for breast cancer incidence and per person intake of butter, cheese and green vegetables, suggesting a causal connection between breast cancer mortality and the consumption of these foods.

- 2048 COMPARATIVE STUDY ON GEOGRAPHICAL DISTRIBUTION OF HUMAN AND CATTLE LEUKOSIS (E.) Khokhlova, M. P. (Min. Publ. Hlth., USSR, Moscow) and P. P. Rakhmanin. *Bibl Haemat* 36:654-658, 1970.

High mortality rates from leukosis and other lymphoid and hematopoietic malignancies were found to occur in Lithuania, Latvia and Estonia, areas where the incidence rate of leukosis among cattle is also high. In Latvia, areas where the mortality among humans from leukosis was below 7 cases/100,000 population were areas where the mortality among cattle from leukosis was below 20 cases/100,000 head of cattle;

areas where the mortality among humans from leukosis was above 10 cases/100,000 were areas where the mortality from leukosis among cattle was above 100 cases/100,000. Cases of human leukosis occurring in narrowly localized areas (e.g., one farm or adjacent farms) were often recorded from areas with a high prevalence of leukosis in cattle herds.

- 2049 DEATHS FROM LUNG CANCER IN AUSTRALIA. (E.) McCall, M. G. (Dept. Med., U. Western Australia, Perth) and N. S. Stenhouse. *Med J Aust* 1(10):524-525, 1971.

Deaths from lung cancer in Australia recorded between 1962-1966 were surveyed to examine mortality from this condition among various immigrant groups in Australia. The death rate for native-born Australians from cancer of the lung was found to be significantly lower than the death rate for immigrants from England, Wales and Scotland. Among persons 40-49-yr-old, there were 16 deaths/100,000 population among the native-born, 28 among English and Welsh immigrants, and 44 among Scots immigrants. The mortality from lung cancer among immigrants to Australia was lower than the mortality among native-born Scots, Englishmen and Welshmen who remained in their homelands. Among immigrants to Australia, age at date of immigration was correlated with lung cancer mortality; those immigrating at an average age of less than 25-yr appeared to show a subsequent lung cancer rate similar to the rate for native-born Australians, while those immigrating to Australia at a more advanced age had increased risks of developing lung cancer. The results were thought to indicate that air pollution played an important role in the genesis of lung cancer in the immigrant groups.

- 2050 A PRELIMINARY REPORT ON THE THYMIDINE LABELING INDICES AND KINETICS OF CELL PROLIFERATION IN SELECTED MORRIS HEPATOMAS. (E.) Looney, W. B. (U. Virginia Sch. Med., Charlottesville), A. A. Mayo, M. Y. Janners, J. G. Mellon, P. Allen, D. Salak and H. P. Morris. *Brit J Cancer* 24(4):826-832, 1970.

Kinetics of cell proliferation and cell loss in Morris hepatomas (H-35tc₂, R-7, 7797, 9611B and 8999) were studied in ACI strain female rats by means of thymidine labeling. The 1 hr thymidine labeling index for the hepatomas ranged from 3.3 to 13.9 and chromosome numbers showed no correlation with the labeling index. The per cent of labeled cells in hepatomas was greater than is found in normal liver before the onset of DNA synthesis and less than the 19.1% at the peak of DNA synthesis in regenerating liver.

- 2051 THE KINETICS OF CELLULAR PROLIFERATION IN NORMAL AND MALIGNANT TISSUES: A REVIEW OF METHODOLOGY AND THE ANALYSIS OF CELL POPULATION KINETICS IN HUMAN TISSUES. (E.) Fabrikant, J. I. (U. Connecticut Sch. Med., Farmington). *Amer J Roentgen* 111(4): 700-711, 1971.

Kinetic parameters of cellular proliferation were ascertained in normal, neoplastic and inflammatory

tissues of the larynx and adjacent tissues from more than 200 patients. Neoplastic tissues included benign squamous cell papillomas of the larynx and malignant squamous cell carcinoma of the larynx. Sites of cell proliferation were determined by monitoring incorporation of tritiated thymidine in cells. In normal tissues, the label was uniformly distributed among zones of proliferation, while in inflammatory tissues, higher labeling indices were found in areas of acute inflammatory cell infiltration. In neoplasms, labeled cells appeared in clusters at different sites. The rate of cell proliferation varied widely in different tissue samples; however, the variation for tumors was comparable to that for normal tissues, and frequently less than that for inflammatory lesions. The duration of the DNA synthesis period (i.e., the duration of the S phase in mitosis) was greater in malignant than in benign tumor cells and was at a minimum in normal cells.

- 2052 BIRTH, DEATH AND NET GROWTH OF NORMAL TRANSFORMING, NEOPLASTIC AND MALIGNANT CELL LINES: DECREASE OF DEATH RATE IN NEOPLASTIC ALTERATION. (E.) Norrby, K. (Dept. I, Path., U. Göteborg, Sweden) and J. Mellgren. *Path Europ* 6(1):56-74, 1971.

Growth kinetics of cell populations were observed in normal and neoplastic human and animal cell cultures; material included fetal normal and juvenile normal human fibroblast-like cell lines from skin and lung, normal fetal cell lines transformed by SV40, an established tumor line derived from an osteogenic sarcoma in a 15-yr-old girl, normal hamster embryo fibroblasts, and spontaneous and SV40-induced hamster sarcomas. Birth and death of cells in the cultures were observed and measured by means of a cinemicrographic technique. The "death index" of cells was expressed as a percentage of the effective birth rate of cells. It was found that the death index of human normal fetal and juvenile cells was 17-19%, while that for human virus-transformed cells and human juvenile neoplastic cells was about 7%. Death indices for normal and neoplastic cells were 27% and 6%, resp. Initially during the process of cell transformation, both birth and death rates of cells rose; this stage was followed by a period of fluctuating death rates in transformed cultures, which was in turn followed by a period of low cell death rate.

- 2056 N-ACETYLATION OF ARGININE-RICH HEPATOMA HISTONES. (E.) Byvoet, P. (Div. Biol. Sci., U. Florida, Gainesville) and H. P. Morris. *Cancer Res* 31(4):468-470, 1971.

Rats with hepatomas and normal rats were given i.p. injections of 100 μ C 14 C-L-alanine/kg to label liver cell histones and 2 mC/kg 3 H-sodium acetate to label histone N-acetyl groups. Decay rates of the N-acetyl groups in the combined arginine and slightly lysine-rich histones from normal and neoplastic tissues were observed. The $t_{1/2}$ in hr for the histone N-acetyl group turnover in Morris hepatoma 3924A and normal liver of Buffalo rats was 1.5 and 1.9, resp. In Novikoff hepatoma cells the $t_{1/2}$ of the histone N-acetyl group was 21 hr; the $t_{1/2}$ for L-alanine- 14 C-labeled histones was 41 hr. The latter figure was similar to the values obtained for L-alanine- 14 C-labeled histones in all normal and neoplastic tissues. In general, the N-acetyl groups turned over much more rapidly than whole histones or DNA, differences between N-acetyl group half-lives and whole histone group half-lives in Morris hepatoma cells often approaching a factor of 10.

- 2057 CHANGES IN PHOSPHOLIPID METABOLISM OF A TUMOR TARGET CELL DURING A CELL-MEDIATED CYTOTOXIC REACTION. (E.) Koren, H. S. (Max Planck Inst. Immunobiol., Freiburg, Germany), E. Ferber and H. Fischer. *Biochim Biophys Acta* 231(3):520-526, 1971.

C57Bl mice were given i.p. injections of 3×10^7 viable DBA/2 ascites mastocytoma cells; 10-11 days thereafter, the spleens of these mice were extracted and lymphocytes were prepared from them for incubation with mastocytoma cells. Phospholipid metabolism in mastocytoma cells treated with spleen lymphocytes of immunized and unimmunized mice was observed by incubating tumor cells with 14 C-labeled oleic acid and lysolecithin. Mastocytoma cells alone incorporated label into membrane lecithin to the extent of 70% and 18% into neutral lipids. Normal lymphocytes caused a decrease in lecithin labeling in mastocytoma cells, and immune lymphocytes caused a 2-3-fold decrease. The degradation of lecithin in cultures of mastocytoma cells incubated with immune lymphocytes proceeded at a more rapid rate than did lecithin degradation in untreated mastocytoma cells or in mastocytoma cells treated with normal lymphocytes.

- 2058 BIOCHEMICAL CHANGES OF THE LIPID IN BIOPSIED LIVERS OF PATIENTS WITH MALIGNANT NEOPLASTIC DISEASES. (E.) Nakazawa, I. (Tohoku U. Sch. Med., Sendai, Japan) and S. Yamagata. *Tohoku J Exp Med* 103(2):129-139, 1971.

Human liver biopsies of 19 patients with malignant neoplastic disease, 26 patients with benign hepatic disease, 2 patients with benign hepatic disease with gastric cancer and 14 controls were subjected to histological examination and lipid analysis by means of thin layer chromatography and gas liquid chromatography. Results revealed a higher content of $C_{20:4}$ and lower $C_{14:0}$ and $C_{18:1}$ fractions in livers of patients with

malignancies compared to controls, while the group with benign hepatic disease showed an increase in the percentage of $C_{14:0}$, $C_{16:1}$ and $C_{18:1}$ and a decrease in percentage of $C_{18:0}$, $C_{18:2}$, $C_{20:4}$, and $C_{22:5}$. In the phospholipid fraction, a significant decrease in the percentage of $C_{14:0}$ was noted in malignant cases, and in 7 cases of benign hepatic disease no significant difference was noted in the percentage of fatty acids compared with the control group. In 7 cases of benign hepatic disease a significant decrease was recognized in the percentage of $C_{18:2}$ while values obtained from the malignant cases were similar to the control group. Content of the fatty acid in the phospholipid fraction of the human liver revealed a mean value of 15.08 mg/g liver in malignant cases compared with the mean value in 11 non-malignant cases of 12.24 mg/g liver and in 9 cases of benign hepatic disease 10.43 mg/g liver. The fatty acid content in the triglyceride fraction gave a mean value of 5.05 mg/g liver for 19 malignant cases compared with the mean of 8.07 mg/g liver for 11 non-malignant cases and 6.76 mg/g liver for 9 cases with benign hepatic diseases.

- 2059 HYDROCORTISONE: INHIBITION OF DNA SYNTHESIS AND MITOTIC RATE AFTER LOCAL APPLICATION TO MOUSE EPIDERMIS. (E.) Hennings, H. (U. Wisconsin Med. Ctr., Madison) and K. Elgjo. *Virchow Arch Zellpath* 8(1):42-49, 1971.

Female hairless mice were given topical doses of 10, 50, 100 or 250 μ g hydrocortisone on the dorsal epidermis; 1-48 days later, mice were given i.p. injections of 3 H-thymidine and 30 minutes before sacrifice, the incorporation of the 3 H label into epidermal cells was examined to determine the effect of hydrocortisone treatment on DNA synthesis. The highest dose of hydrocortisone inhibited DNA synthesis by more than 40% at all times tested between 4 and 24 hr; the inhibition of DNA synthesis produced by smaller doses of hydrocortisone was more gradual in onset, and animals given smaller doses of hydrocortisone recovered normal rates of DNA synthesis sooner than animals given 250 μ g of hydrocortisone. By 48 hr after hydrocortisone treatment, DNA synthesis had recovered in all animals. At all doses of hydrocortisone tested, the maximal inhibition of DNA synthesis was observed 12 hr after treatment. The inhibitory effect of hydrocortisone was not affected by the time of day at which the compound was administered. Inhibition of DNA synthesis by hydrocortisone was accompanied by a decrease in mitotic activity, indicating that cells in the G1 and G2 phase of mitosis were susceptible to the inhibitory effects of hydrocortisone. When epidermal chalone was used to treat mouse skin in addition to hydrocortisone it was found that the former agent did not affect the inhibitory effect of hydrocortisone. When croton oil was applied to mouse skin following hydrocortisone, the increase in DNA synthesis usually seen with croton oil was reduced.

- 2060 INTRACELLULAR HYDROGEN TRANSPORT SYSTEMS IN ACUTE LEUKAEMIA. (E.) Stuart, J. (Child Hosp., Birmingham, England), J. S. Simpson and J. R. Mann. *Brit J Haemat* 19(6):739-748, 1971.

Bone marrow smears from 10 children in the acute or remission state of acute lymphoblastic leukemia and 10 children with no known disease were incubated at 37° for 90 min in freshly prepared incubation solution containing nitroblue tetrazolium, fixed for 10 min in a 40% formalin solution following incubation, counterstained for 10 min with aqueous methyl green, and studied by means of a scanning and integrating microdensitometer set at the wavelength of green light. Marrow enzyme scores for small lymphocytes for 10 patients in hematological remission were not significantly different from controls with the exception of glucose-6-phosphate dehydrogenase which showed a significantly higher activity in the non-leukemic patients. The mean enzyme scores for blast cells of 24 children newly diagnosed or in relapse showed a significant increase in extramitochondrial lactate dehydrogenase, malate dehydrogenase and 3-hydroxybutyrate dehydrogenase with no significant increase in the activity of intramitochondrial respiratory dehydrogenases. Exposure to hyperbaric oxygen prior to incubation resulted in no significant alteration in dehydrogenase activity. The net transhydrogenation effect was significantly greater for both the blast cells of leukemic patients and PHA-transformed lymphocytes from normal adults compared with the small lymphocytes.

2061 CYTOPLASMIC AND NUCLEAR GLYCOGEN SYNTHESIS IN NOVIKOFF ASCITES HEPATOMA CELLS. (E.) Karasaki, S. (Hosp. Notre-Dame, Montreal, Quebec, Canada). *J Ultrastruct Res* 35(1-2):181-196, 1971.

Novikoff ascites hepatoma cells from transplanted tumors in rats were incubated with ³H-labeled D-glucose, and on electron microscope examination were found to have incorporated the label in β-type glycogen particles in the cell cytoplasm. Three minutes after incubation with labeled D-glucose, autoradiography showed that the label was localized mainly in glycogen foci which themselves showed no marked alteration from their normal state. Treatment of incubated cells with α-amylase resulted in an almost complete extraction of glycogen particles. Between 5-15 min after incubation of ascites cells with labeled D-glucose a significant growth of the glycogen area occurred in cell cytoplasm, accompanied by labeling of the newly formed glycogen particles. The number of α-type glycogen particles was seen to have increased. By 30-60 min after incubation, the size and number of glycogen particles had increased to maximum values; in 1 case a single glycogen island occupied more than half of the cytoplasm in the cell. The number of α-type glycogen particles and the number of intranuclear glycogen particles also increased by 60 min after incubation. By 120 min after incubation with labeled D-glucose, the size and number of glycogen foci in tumor cells had begun to decline.

2062 CHANGES IN HYBRIDIZABLE NUCLEAR RNA DURING THE NEOPLASTIC DEVELOPMENT OF MOUSE MAMMARY CELLS. (E.) Turkington, R. W. (Duke U. Med. Ctr., Durham, N. C.). *Cancer Res* 31(4):427-432, 1971.

Normal mammary glands, hyperplastic alveolar nodule outgrowths derived from primary nodules, spontaneous mammary carcinomas and serially transplanted mammary carcinomas of C3H/HeJ female mice were used to prepare nuclear tritium-labeled RNA and DNA which were compared by techniques of RNA-DNA hybridization and hybridization competition. The direct hybridization reaction did not detect differences in the RNA populations derived from hyperplastic alveolar nodule outgrowths or spontaneous carcinomas. Mammary gland RNA competed incompletely with hyperplastic alveolar nodule RNA, and spontaneous carcinoma RNA; hyperplastic alveolar nodule RNA competed incompletely with RNA from spontaneous carcinomas; RNA from the spontaneous carcinomas competed incompletely with RNA from the transplanted carcinomas demonstrating that successive stages of neoplastic development are characterized by a discreet increment in the diversity of hybridizable nuclear RNA species formed.

2063 ¹³¹I-LABELED COLLOIDAL HUMAN SERUM ALBUMIN IN THE STUDY OF RETICULOENDOTHELIAL SYSTEM FUNCTION: III. PHAGOCYTOSIS AND CATABOLISM COMPARED IN NORMAL, LEUKEMIC AND IMMUNOSUPPRESSED HUMAN SUBJECTS. (E.) Palmer, D. L. (U. Colorado Med. Ctr., Denver), D. Rifkind and D. W. Brown. *J Infect Dis* 123(5):465-469, 1971.

Eight immunosuppressed patients with recent renal homograft transplantations receiving large doses of azathioprine and prednisone with sustained renal functions and no evidence of hepatic or cardiovascular decompensation (6 males and 2 females, 16-45 yr) and 5 leukemia patients (4 females and 1 male, 48-68 yr) were injected i.v. with human serum albumin labeled with ¹³¹I to measure phagocytosis; its rate of appearance in the blood was used to measure the catabolism of the colloid. Both the leukemic and transplant patients had significantly greater amounts of slowly phagocytized labeled human serum albumin than the normal patients; there was no relationship between the chronic and acute type of leukemia or duration of the disease and the rate of phagocytosis. The duration of the lag phase varied between 0 and 16.0 min for all patients with no significant difference noted among the groups; however, catabolic breakdown was significantly more rapid for the leukemic patients compared to the other groups with a value of 318 min for the leukemic group and 686 min and 573 min for the normal and transplant patients, resp. The initial phagocytic rate, the rate of catabolism and the amount of material not rapidly cleared appeared to be independent of each other.

2064 TYROSINE HYDROXYLASE IN NEUROBLASTOMA. (E.) Imashuku, S. (Kyoto Prefect. U. Med., Japan), E. H. Labrosse, E. M. Johnson, Jr., V. H. Morgenroth, III and N. Zenker. *Biochem Med* 5(1):22-29, 1971.

Two neuroblastomas excised from Negro children were assayed for tyrosine hydroxylase activity; tyrosine hydroxylase in the tumor tissues was found to require tetrahydropyridine (DMPH₄). Tyrosine hydroxylase

activity, measured in nmoles/25 mg/10 min of dopa formed, was zero in the absence of DMPH₄ in both tumors, and 0.874 and 0.183 in the 2 tumors in the presence of DMPH₄. Ferrous ion enhanced the level of tyrosine hydroxylase activity in the presence of DMPH₄; enzyme values for the 2 tumors in the presence of DMPH₄ and Fe²⁺ were 1.46 and 0.681, resp. Catecholamines and other inhibitors, including L-dopa, dopamine, DL-norepinephrine, DL- α -methyl-tyrosine, and benzimidazole-5(6)-DL-alanine dihydrochloride inhibited tyrosine hydroxylase activity in the neuroblastomas to the same extent as they inhibited the enzyme in bovine adrenal tissue, suggesting that neuroblastoma tyrosine hydroxylase was normally susceptible to feedback inhibition.

2065 CONTROL MECHANISMS OF ADENINE NUCLEOTIDE METABOLISM OF ASCITES TUMOR CELLS. (E.)

Yushok, W. D. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.). *J Biol Chem* 246(6):1607-1617, 1971.

Changes in the adenine nucleotide quotient [(ATP)(AMP)/(ADP)²] of Ehrlich ascites cells grown in female white Swiss mice of the ICR strain in response to adenosine, inosine, L-glutamine, and inorganic phosphate were studied. Aerobic incubation with adenosine and inosine increased the ATP, AMP and total adenine nucleotide content; added adenosine doubled the adenine nucleotide within 60 min. Glucose in combination with L-glutamine increased the adenine nucleotide by 0.5 μ mole/ml of cells in 30 min in the presence of added inorganic phosphate but had no effect in its absence; in the absence of glutamine, glucose did not significantly affect the steady state total adenine nucleotide content. In the absence of Mg²⁺, L-glutamine alone, adenosine alone, or both in combination increased the total adenine nucleotide content, 18, 46, and 58%, resp.; the addition of Mg²⁺ resulted in an additional accumulation of the total adenine nucleotide content, increased the ATP:ADP ratio and the adenine nucleotide quotient but had no effect on glucose utilization or oxygen uptake. Extensive changes in the levels of adenine nucleotide were found in 1 min after addition of 2-deoxyglucose; more than half the ATP content disappeared and ADP and AMP showed a 2- and 3-fold increase, resp., with accompanying decreases in ATP:ADP ratios and adenine nucleotide quotient. The addition of glucose prevented the ATP- and total adenine nucleotide-depleting effects in a 5-min period. Glyoxylate increased AMP and inorganic phosphate levels and had little effect on total adenine nucleotides.

2066 MUCOSUBSTANCES IN NEOPLASM OF THE HUMAN COLON AND RECTUM. (E.) Subbuswamy, S. G. (Newcastle Gen. Hosp., England). *Gut* 12(3):200-207, 1971.

Sections from normal colon and rectum secreted sulfated mucosubstances from the deeper parts of the mucosa and nonsulfated mucosubstances from surface mucosa; little neutral mucosubstance was seen in normal mucosa. Benign colonic and rectal tumors, including adenomatous polyps,

papillary adenomas and villous papillomas, secreted primarily nonsulfated acid mucosubstances, with little sulfated mucosubstances in evidence. When sulfated mucosubstances appeared in association with benign tumors, they were usually confined to deeper parts of the mucosa. Malignant carcinomas of colon and rectum contained very little mucosubstances with 3 of 32 specimens showing almost no secretion. Of the 29 cases of malignancy in which mucosubstances were seen, one case contained only neutral mucosubstance, and 10 were made up of almost entirely acid nonsulfated mucosubstances. No sulfated mucosubstances were seen in 12 cases. In tissue adjacent to tumors, a zone of minimal mucosubstance secretion was seen; outside this zone, most mucosubstances were acid nonsulfated. In other specimens of tissue taken from the vicinity of tumors, mucosubstances were almost entirely sulfated; in the latter areas, secretion of mucosubstances was minimal.

2067 ACTIVITIES OF UREA CYCLE ENZYMES IN TUMOR-BEARING MICE. (E.) Sano, M. (Nagoya U. Sch. Med., Japan). *Nagoya J Med Sci* 33(4):315-28, 1971.

Female SMA mice were given i.p. inoculations of Ehrlich ascites tumor cells to induce tumors and killed 2-16 days after inoculation, at which time arginase activity in their livers was assayed. While arginase activity in livers of tumor-free mice did not vary significantly, arginase activity in Ehrlich tumor-bearing mice increased between 2-16 days postinoculation from a value of 601,000 μ moles of urea formed/100 g body wt/hour at day 2 to 1,338,000 μ moles/100 g/hour at day 16. Tumor-bearing mice showed decreased carcass wt by day 16. In mice with solid tumors which weighed less than 10% of the carcass wt of the mouse, hepatic arginase was comparable to that in tumor-free mice, while in mice bearing solid tumors weighing more than 10% of carcass wt, arginase activity was increased significantly. In a related experiment, mice which had been inoculated with Ehrlich tumor cells were maintained alive and their urine was collected every 2-3 days to determine the rate of urea excretion. Urea excretion in tumor-bearing mice decreased moderately during the period 6-12 days postinoculation, amounting to 96 mg/24 hr/mouse; at 16 day postinoculation, however, urea excretion rose to 147 mg/hr/mouse. Hepatic arginase was markedly increased in tumor-bearing mice on high protein diets and in tumor-free mice given 3 injections of prednisolone hemisuccinate. Arginase activity in the livers of mice given Ehrlich ascites tumor implants and which were adrenalectomized was significantly lower than hepatic arginase activity in tumor-bearing intact mice.

2068 A NEW PROTEOLIPID APPARENTLY ASSOCIATED WITH CANCER. (E.) Skipski, V. P. (Sloan-Kettering Inst. Cancer Res., Rye, N. Y.), M. Barclay, F. M. Archibald, T. P. Lynch, Jr. and C. C. Stock. *Proc Soc Exp Biol Med* 136(4):1261-1264, 1971.

A proteolipid was isolated from lipid extracts of Walker carcinosarcoma by silicic acid column chromatography with stepwise gradient elution in chloroform-methanol mixtures. The lipid was soluble in chloroform-methanol mixtures and insoluble in weak salt or water solutions. The new lipid contained less protein than proteolipids previously isolated from bovine and human nervous tissues. The new lipid was present in transplanted Walker rat tumors and in mouse sarcomas. Of normal tissues, only the spleen had significant amounts of the new lipid. Whole serum lipid extract from tumors contained the new proteolipid. The new lipid was also found in the sera of certain cancer patients; sera from normal subjects was consistently negative for the new lipid.

- 2069 ³⁵SULPHUR UPTAKE IN THE MUCOSA ADJACENT TO CARCINOMA OF THE LARGE INTESTINE. (E.) Filipe, M. I. (Westminster Med. Sch., London, England). *Histochem J* 3(1):27-35, 1971.

Surgical specimens from human carcinoma of the colon and rectum were treated with ³⁵S and the uptake of the isotope was observed in normal mucosa and in mucosa adjacent to the carcinomas. The lower half of the normal colonic crypt contained sulfated acid mucosubstances, and the upper half and surface epithelium of the crypt contained a mixture of sulfated and non-sulfated acid mucins, probably sialic acid residues. In mucosa adjacent to tumors, a gradual decrease of sulfated material was seen together with an increase in a non-sulfated acid mucosubstance which was thought to be sialic acid-rich mucosubstance. ³⁵S was absorbed along the crypt and surface epithelium in normal mucosa; in mucosa adjacent to carcinomas, the isotope was incorporated by surface epithelium only or not at all.

- 2070 REVERSION OF THE INHIBITORY EFFECT OF BUSULPHAN ON BONE MARROW CELL PROLIFERATION BY CHLORAMBUCIL. (E.) Niskanen, E. (2nd Dept. Path., U. Helsinki, Finland), T. Rytömaa and E. Kivilaakso. *Acta Path Microbiol Scand* 79(2): 102-108, 1971.

Male rats were given i.p. injections of 12 mg/kg of busulphan and chlorambucil, and serum drawn from treated rats was incubated with bone marrow cell samples taken at the same time and labeled with ³H-thymidine for monitoring cell proliferation. Serum taken 2-8 days after combined chlorambucil-busulphan treatment did not markedly affect the incorporation of tritiated thymidine into bone marrow cells. By day 8 after treatment, incorporation of label by bone marrow cells incubated with sera from treated rats was 15-97% higher than that in bone marrow cells not incubated with sera from treated rats. Sera taken on day 9 after treatment increased the uptake of ³H-adenine by bone marrow cells by 21.6%. Although before day 9 after treatment, the stimulation of ³H-thymidine by bone marrow cells was more pronounced in cultures incubated with sera taken from rats treated with chlorambucil alone than it was in cultures incubated with sera taken from rats treated with both chlorambucil and busulphan,

by day 9 sera from rats given combined treatment showed the higher values. It was thought that sera from rats given the combined busulphan-chlorambucil treatment contained a proliferation-stimulating factor resembling antichalone.

- 2071 INITIATION OF POLYSOME FORMATION IN MOUSE SARCOMA 180 ASCITES CELLS: UTILIZATION OF CYTOPLASMIC MESSENGER RIBONUCLEIC ACID. (E.) Lee, S. Y. (Tufts U. Sch. Med., Boston, Mass.), V. Krsmanovic and G. Brawerman. *Biochemistry* 10(5): 895-900, 1971.

The study of mRNA-ribosome interaction was studied in mouse sarcoma 180 ascites cells by means of uridine labeling. Incubation of sarcoma cells in the absence of nutrients for 30 min led to nearly complete disappearance of polysomes from the cytoplasm with a return of polysome formation with the addition of nutrients as early as 3 min post-addition with maximum conversion appearing within 10 min. Polysome formation in cells exposed to high levels of actinomycin D followed a similar pattern until a 60-min recovery period had elapsed when monomers again appeared in the treated cells. Heterodisperse RNA-containing structures are apparently released from polysomes during starvation and reutilized for polysome formation after addition of amino acids.

- 2072 THE PRESENCE IN NORMAL LIVER OF HIGHLY ACTIVE CANCER CELL GROWTH INHIBITING SUBSTANCES. (Fr.) Chany, E. (Inst. Cancer Res., Villejuif, France) and C. Frayssinet. *C R Acad Sci* 20:2644-2647, 1971.

The addition of extracts of normal liver cell homogenates from rat, hamster, mouse and beef to cell cultures of rat hepatoma LF, rat, mouse or hamster embryo fibroblasts and KB mouse cells elicited marked inhibition of cell growth. Inhibition was distinctly noticeable at 24 hr and marked at 48 hr. Extracts of hepatoma cells caused no inhibition of the above cells at 24 hr, and only slight effects at 48 hr. The inhibition by liver cell extract of cell growth occurred with 5 µg/ml protein or 50 µg/10⁶ culture cells; hepatoma extracts in amounts of 250 µg/ml protein did not result in marked inhibition of growth. The effects shown were apparently not related to arginase nor to removal of essential cell nutrients by factors other than arginase.

- 2073 HEPATOCELLULAR GLYCOGENOSIS AND HEPATOMA DEVELOPMENT IN MAN. (Ger.) Bannasch, P. (Path. Inst. U. Würzburg, Germany) and O. Klinge. *Virchow Arch Path Anat* 352(2):157-164, 1971.

Electron and light microscopic examinations of biopsy specimens from 12 hepatocellular carcinomas and 5

adenomas in humans were analyzed, with particular reference to glycogen storage. Although the majority were found to be poor in glycogen or glycogen free, 2 carcinomas and 4 adenomas showed massive glycogen storage. The glycogen-poor tumors were composed mainly of basophil cells, with only a few epithelial cells in which glycogen stores could be ascertained. The glycogen-rich cells were found to be close to "clear" cells, and transformation from the light storage cells to the dark tumor cells was frequently observed. In one case it was possible to obtain biopsies at 3 different stages of the tumor development from which it could be seen that the glycogen content varies during the tumor formation. The results confirm the finding in experimental animals that the metamorphosis of the hepatic cells during cancer formation in man is closely related to glycogenesis.

- 2074 POLYAMINE ACCUMULATION AND BIOSYNTHESIS IN A MOUSE L1210 LEUKEMIA. (E.) Russell, D. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and C. c. Levy. *Cancer Res* 31(3):248-251, 1971.

Ornithine decarboxylase activity, putrescine synthesis and spermine synthesis were observed in tissues of a rapidly proliferating leukemia induced in mice by the injection of ascites cells 4-10 days prior to the enzyme assay. By 4 days after inoculation with tumor cells, ornithine carboxylase activity in the leukemic mice had attained levels 8 times higher than those attained by normal control mice, but returned to near normal levels by 6 days postinoculation. The enzyme which synthesizes spermidine in leukemic rats was 4-fold above the levels in normal controls by 4 days after inoculation of tumor cells and was still 2-fold above normal at 10 days. The enzyme which forms putrescine was also elevated in leukemic rats. Concentrations of putrescine and spermidine in tumor tissue were increased by nearly 100% over the concentrations of these compounds in any other mouse tissue. Agents which increase the survival time of the tumor-inoculated mice, including 5-[3,3-bis(2-chloroethyl)-1-triazeno]imidazole-4-carboxamide and cytosine arabinoside caused decreases in the ability of the tumor to accumulate polyamines.

- 2075 DIFFUSIBLE FACTORS FROM MALIGNANT CELLS WHICH AFFECT EPIDERMAL SURVIVAL AND DIFFERENTIATION. (E.) Daniel, M. R. (Strangeways Res. Lab., Cambridge, England). *Brit J Cancer* 24(4): 712-718, 1970.

The effect of contact with malignant fibroblasts on embryonic chick epidermis cultured *in vitro* was studied. After 4 days, abnormalities ranging from abnormal differentiation to complete degeneration appeared when epidermal cultures were grown on a 25 μ m-thick cellulose membrane overlying malignant fibroblasts but not on a 50 μ m thick membrane. The use of a semipermeable membrane revealed keratinization without cell degeneration or differentiation. When whole skin was grown on clumps of viable malignant cells, the epidermis remained healthy and may cultures differentiated normally. However,

in some instances epidermal thickening and folding was observed. Malignant dermal fibroblasts apparently produced 2 substances which influenced survival and differentiation of embryonic epidermis; one, of small molecular size, affected the differentiation of the tissue while the other, a macromolecule, caused degeneration.

- 2076 NUCLEIC ACID METABOLISM IN PROLIFERATING AND DIFFERENTIATING COLONIC CELLS OF MAN AND IN NEOPLASTIC LESIONS OF THE COLON. (E.) Troncale, F. (Cornell U. Med. Coll., New York, N.Y.), R. Hertz and M. Lipkin. *Cancer Res* 31(4):463-467, 1971.

Varying levels of thymidine kinase, thymidine phosphorylase and adenine and hypoxanthine phosphoribosyltransferase were found to characterize different stages of cell differentiation in the normal colon. Most cells which synthesized DNA were located in the lower third of the colonic crypts, below cell position 30, while few cells were in DNA synthesis as they reached the upper third of the crypts. In the normal colonic crypt, there was a 4-fold decrease in the activity of thymidine kinase in the upper as compared to the lower third of the crypts, indicating that the level of thymidine kinase activity drops abruptly as cells migrate through the middle third of the crypts. A 4-fold increase in adenine phosphoribosyltransferase was found as cells migrated from the lower to the upper third of the colonic crypts, and a lesser increase was seen in hypoxanthine phosphoribosyltransferase. A decrease in the activity of thymidine phosphorylase was seen as cells migrated to the upper third of the colonic crypts. Comparative enzyme activities were also investigated in cells removed from the surface of the colonic mucosa and from the surface of polypoid lesions having the appearance of adenomas and carcinomas in human subjects. Thymidine kinase activity was greater in villous adenoma and carcinoma cells than in nonneoplastic cells, approximating the levels of activity found in proliferating cells of normal colonic tissue. Adenine phosphoribosyltransferase activity was significantly greater in the mature surface cells of normal colon than in other specimens; activity of this enzyme decreased in cells of polyps of increasing size. Hypoxanthine phosphoribosyltransferase activity was higher in mature colon cells and in small hyperplastic polyps than in the other lesions. The activity of thymidine phosphorylase in hyperplastic tissue was similar to the activity of this enzyme in proliferative cells.

- 2077 THE FORMATION OF MELANIN IN MUSCLE CELLS AFTER THE DIRECT TRANSFER OF RNA FROM HARDING-PASSEY MELANOMA CELLS. (Ger.) Grässmann, A. (Inst. Physiol. Chem., Free U. Berlin, Germany) and M. Grässman. *Hoppe-Seyler Z Physiol Chem* 352(4): 527-532, 1971.

Incubation over 20 hr of cultured Harding-Passey melanoma cells with ^3H -L-DOPA leads to incorporation of isotope (shown autoradiographically) in the cytoplasm of the melanoma cells, but label was not

incorporated over 48 hr incubation by striated muscle cells. The same negative findings were obtained when the isotope was injected by micro-annula directly into the muscle cells. Micro-injection of melanoma cell RNA into the muscle cells prior to incubation with isotope resulted in 80% DOPA incorporation. Alkaline hydrolysis or reaction with ribonuclease of the melanoma cell RNA prior to injection prevented the incorporation of DOPA; pro-nase or DNase treatment had no effect. Injection of rat liver RNA into muscle cells did not elicit isotope incorporation. Cycloheximide prevented incorporation of DOPA into the melanin of Harding-Rassey melanoma cells as well as in muscle cells injected with melanoma cell RNA.

78 PREFERENTIAL INHIBITION BY 5 BROMODEOXY-URIDINE OF THE SYNTHESIS OF TYROSINE AMINO-TRANSFERASE IN HEPATOMA CELL CULTURES. (E.) Stell-gen, R. H. (Dept. Biochem., Biophys., U. California, San Francisco) and G. M. Tomkins. *J Molec Biol* 56(1):177-182, 1971.

rat hepatoma cells incubated for 1 or 2 generations with 5-bromodeoxyuridine (BDU) showed a 75% reduction in tyrosine aminotransferase after 24 hr in culture; replacing BDU with thymidine in the culture medium reversed the BDU effect on tyrosine aminotransferase, and enzyme values returned to normal by 120 hr in culture. Exposure of rat hepatoma cells to BDU for more than 2-3 generations produced a decrease in the rate of cell growth. Total cellular protein and RNA were only slightly reduced in cultures grown with BDU; of 5 other enzymes examined, including 4 dehydrogenases and an acid phosphatase, none showed any change in specific activity for 1-2 cell generations of incubation with BDU. Incorporation of BDU into all DNA seemed to be required in order for it to affect tyrosine aminotransferase. The actual decrease in tyrosine aminotransferase produced by BDU was apparently the result of a lowered rate of synthesis of the enzyme in the cell.

79 THE LYMPHOCYTE AND HUMAN LUNG CANCERS. (E.) Richters, A. (U. Southern California Sch. of Medicine, Los Angeles), R. P. Sherwin and V. Richters. *Cancer Res* 31(3):214-222, 1971.

Lymphocyte interactions were observed among tissue explants taken from human lung epidermoid cancer, adenocarcinoma, undifferentiated carcinoma, and non-neoplastic lung tissues including epithelial cells, spindle cells and macrophages. "Lymphocyte interactions" consisted of random movements of lymphocytes among neoplastic and nonneoplastic human lung cells, and special activities including clustering, congregation and emperipolesis involved attachments of 3 or more lymphocytes to other cells or penetration of lymphocytes into a cell. Lymphocytes were seen to migrate from 82% of cancer tissue explants. Cancer explants showed reduced random and special lymphocyte interactions compared to nonneoplastic tissues; 8% of cancer cells showed random interactions compared

with 15-65% of normal cells, and 17% of cancer cells showed special interactions compared with 10-30% of normal cells. Nonneoplastic cells derived from cancer-free subjects showed more random lymphocyte interactions than nonneoplastic cells derived from cancer-bearing subjects; this relationship between cancer-free and cancer-bearing subjects' nonneoplastic cell explants was reversed for special lymphocyte interactions. Nonneoplastic cells from cancer-bearing subjects with adenocarcinoma or undifferentiated carcinoma had random lymphocyte interaction levels of 34.8 and 13.8%, resp., while random interaction levels for nonneoplastic cells from patients with epidermoid cancer were less than 1%. Random lymphocyte interactions for epidermoid cancer cells were 3 times higher than for adenocarcinoma cells, and 5 times higher than for undifferentiated cancer cells; special lymphocyte interactions were lower in epidermoid cancer cells than in the other 2 types of cancer cell. Among the special lymphocyte interactions, emperipolesis was the dominant response to cancer cells.

2080 A HISTOCHEMICAL STUDY OF ALKALINE AND ACID NUCLEASE ACTIVITY IN THE HUMAN BRAIN COMPARED TO THE INCIDENCE OF MALIGNANT TUMOURS. (E.) Taper, H. S. (Dept. Neuropath., U. Louvain, Belgium), J. M. Brucher and G. Doyen. *J Neurol Sci* 12(4):369-382, 1971.

Acid and alkaline nuclease activity was assayed in various parts of the normal brain, and associations of acid and alkaline nuclease with brain tumors were explored. The greatest alkaline DNase activity was found in the epithelial cells of the choroid plexus; the apical region of the ependymal epithelium was found to have high alkaline DNase in the cytoplasm of cells, but not in cell nuclei. Brain capillaries, neurons and glial cells were practically negative for alkaline DNase, while leptomeninges showed alkaline DNase activity. Alkaline RNase was distributed in the brain in a manner similar to the distribution of alkaline DNase; however, RNase was present in the endothelial cells of brain capillaries, but alkaline DNase was not. Acid DNase was present in all nerve cells; glial cells had lower levels of acid DNase than nerve cells. Acid RNase was distributed in a manner similar to the distribution of acid DNase. It was found that glial cells, which displayed a low nuclease activity, had a high incidence of malignant tumors, accounting for 26.5% of one series of malignancies. Nerve cells, on the other hand, which demonstrated the highest values for nuclease activity, had the lowest incidence of malignant tumors of all the brain tissues (0.0%).

2081 INCORPORATION OF ^{32}P INTO NUCLEIC ACIDS IN MAMMARY TISSUE OF MICE SUSCEPTIBLE AND RESISTANT TO BREAST CANCER. (E.) Sheth, N. A. (Cancer Res. Inst., Tata Mem. Ctr., Bombay, India), S. V. Bhide and K. J. Ranadive. *J Nat Cancer Inst* 46(4):731-734, 1971.

Mammary tumor-susceptible C3H strain mice, and mammary tumor-resistant C57B1 mice, were given i.p.

injections of 15 μC ^{32}P -labeled sodium phosphate solution; intact and castrate mice 4, 8 and 12-month-old were used. The incorporation of ^{32}P into DNA and RNA of mammary and tumor tissue were compared in the susceptible and resistant strains. In tumor-bearing C3H mice, DNA and RNA in tumor tissue incorporated more label than did other tissues. In both strains, the uptake of ^{32}P into DNA was similar in 4- and 8-month-old mice, and in corresponding C3H groups. In castrate C57Bl mice, the uptake of ^{32}P into DNA in 8-month-old mice was markedly lower than in 8-month-old intact mice, and continued to be low in 12-month-old castrates. Incorporation of ^{32}P into RNA in 8-month-old castrates was comparable to that in 8-month-old intact mice, but incorporation into RNA fell significantly in 12-month-old C57Bl castrates.

- 2082 DEOXYRIBONUCLEIC ACID POLYMERASE ACTIVITY ASSOCIATED WITH A PLASMA PARTICULATE FRACTION FROM PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. (E.) Kiessling, A. A. (Dept. Agric. Chem., Oregon St. U., Corvallis), G. H. Weber, A. O. Deeney, E. A. Possehl and G. S. Beaudreau. *J Virol* 7(2):226, 1971.

DNA polymerase activity in human plasma from patients with chronic lymphocytic leukemia was studied by buoyant density determination and enzyme assay. Enzyme activity from the plasma of an 87-yr-old male diagnosed as having had chronic lymphocytic leukemia for 10 yr without chemotherapy was found to be (by ^3H -dGTP incorporation) 72-125 cpm without detergent, compared to 47-570 cpm with detergent treatment. The polymerase activity of the plasma from a newly diagnosed patient under transfusion therapy during the plasma collection period showed label incorporation ranging from 50-84 cpm without detergent and 80-170 cpm with detergent treatment; in both instances enzyme activity was stimulated by the addition of *Micrococcus lysodeikticus* DNA to the assay mixture, which resulted in increases from 76-525 cpm in the first case and 48-135 cpm in the second case. Banding on isopycnic cesium chloride showed a major band at a density of 1.72 with considerable radioactivity located in the dense regions of the gradient with DNA from one case, and enzyme from this individual had a high rate of DNA synthesis. Absence of particulate enzyme activity in plasma from healthy individuals demonstrated that the activity from the leukemic plasmas was not a measure of low enzyme activity normally found in plasma. However, the possibility that the appearance of DNA polymerase in the plasma particulate fraction from the patient with a 10-yr history of chronic lymphocytic leukemia may have been a secondary effect from the stress of the disease.

- 2083 IMP: AND AMP:PYROPHOSPHATE PHOSPHORIBOSYLTRANSFERASE IN LEUKEMIC AND NORMAL HUMAN LEUKOCYTES. (E.) Smith, J. L. (U. Cambridge Dept. Med., England), G. A. Omura, I. H. Krakoff and M. E. Ballis. *Proc Soc Exp Biol Med* 136(4):1299-1303, 1971.

Leukocytes isolated from venous heparinized blood were incubated with adenine-8- ^{14}C and hypoxanthine-8- ^{14}C and nucleotide formation was determined. The incorporation of substrate at concentrations of 100 μM in the medium was linear over the range 0-6 x 10⁶ leukocytes/ml. The mean peripheral blood leukocyte hypoxanthine-guanine phosphoribosyltransferase activity of 9 patients with acute myelogenous leukemia in bone marrow relapse was significantly greater than normal (0.01 > p > 0.001); the mean activity in leukocytes from patients with acute lymphoblastic leukemia in marrow relapse was somewhat higher than normal level. Leukocytes from all patients had increased mean level of adenine transferase; however, the activities were not significantly greater than normal. The activity of adenine phosphoribosyltransferase was 2.8-7.2 times as great as hypoxanthine phosphoribosyltransferase in normal leukocytes; patients with leukemia showed an adenine enzyme activity of 0.7-7.5 times as active as the hypoxanthine enzyme. Activities did not appear to be correlated to drug therapy or the peripheral cell counts of the patients studied.

- 2084 STUDIES ON β -GLUCURONIDASE AND DNA SYNTHESIS ACTIVITIES IN THE BLADDER TUMORS. (E.) Senda, H. (Sch. Med. Nagoya U., Japan). *Nagoya J Med Sci* 33(3):203-229, 1971.

Twenty-four hour urine specimens from patients, blood serum, exudate from temporary excluded bladders and biopsy material from a bladder carcinoma were studied for β -glucuronidase activity by means of the aglucuron method, disc electrophoresis and autoradiography. β -Glucuronidase activity tended to be high in the morning and low in the afternoon as determined at 3-hr intervals for 24 hr. Enzyme activity in the serum was not always high when activity was high in the urine; no definite pattern of fluctuation was seen. The unit volume activity of the enzyme in 5 patients showed greater day-to-day fluctuation than did the urine enzyme activity. The presence of bacteria in 2 cases revealed increased urinary activity in proportion to the incubation time even though bacterial cultures at the end of 24 hr were negative. Right and left renal urine obtained by ureteral catheter in 5 persons without disease showed no difference in activity from bladder urine, whereas in the presence of bladder tumors β -glucuronidase activity of bladder urine was remarkably high compared to ureteral urine. In normal subjects the minimum value for urinary glucuronidase was 0.10 $\mu\text{g}/\text{ml}/\text{hr}$ and the maximum value was 1.45 $\mu\text{g}/\text{ml}/\text{hr}$ in comparison to serum activity which ranged from 0.18 to 0.84 $\mu\text{g}/\text{ml}/\text{hr}$. In 38 cases of bladder tumor urinary enzyme activity ranged from 1.01 $\mu\text{g}/\text{ml}/\text{hr}$ to 13.40 $\mu\text{g}/\text{ml}/\text{hr}$; administration of D-glucaro-dilactone suppressed these values to normal levels.

- 2085 β -GLUCURONIDASE ACTIVITY IN TUMORS: ACCUMULATION OF RADIOIODINATED PHENOLPHTHALEIN. (E.) Anghileri, L. J. (U. Colorado Med. Ctr., Denver) and E. S. Miller. *Oncology* 25(1):19-32, 1971.

the use of ^{131}I -phenolphthalein glucuronide as a labeling substrate in tumor detection on the basis of β -glucuronidase activity has been studied in Ehrlich carcinoma and melanoma B16-bearing mice following i.p. and i.v. injection. *In vivo* radioactivity distribution 24 hr after i.v. injection decreased as follows: kidney>liver>spleen>tumor>lungs>intestine>pancreas>blood>muscle>stomach; "free" iodide assay produced by the *in vitro* action of β -glucuronidase on labeled glucuronide indicated that only stomach tissue showed deiodinating activity. The stability of the radioiodine tag was also reflected in the whole body counting, in which up to 23% of the activity remained at 30 days after injection; 2 to 7% of the counts was deposited in the liver. Higher radioactivity accumulation in liver, kidneys and intestine was due mainly to their function as detoxication and/or elimination organs; generally, the localization of ^{131}I -phenolphthalein glucuronide in tumors appears to be an excellent index of its β -glucuronidase activity.

2086 GLYCOGEN SYNTHESIS AND GLYCOGEN SYNTHETASE IN RAT ASCITES HEPATOMAS OF LOW AND HIGH GLYCOGEN CONTENT. (E.) Saheki, R. (Res. Inst. Tuberc. Leprosy, Cancer, Tohoku U., Sendai, Japan), Sato and S. Tsuiki. *Biochim Biophys Acta* 230(3): 571-582, 1971.

Male Donryu rats maintained on a commercial rat diet and given glycogen-rich and glycogen-deficient tumor inoculation were used as hosts for tumor cells which were harvested from the peritoneal cavity 4-6 days after inoculation and incubated *in vitro* in either the presence or absence of labeled glucose. In the presence of glucose, glycogen synthesis was initiated at comparable rates in both cell lines, but in the glycogen-deficient line the synthesis rate declined at comparable rates in both cell lines; and in the glycogen-rich tumor the rate of synthesis remained unaffected by glycogen accumulation. In the presence of amygdalin the glycogen-rich tumor cells remained unaffected while those of the glycogen-deficient tumor failed to synthesize glycogen from glucose. The glycogen-rich cells had higher levels of glycogen synthetase activity and lower levels of phosphorylase activity than the glycogen-deficient hepatoma, while the phosphoglucosyltransferase activities in the 2 hepatomas were similar. The glycogen synthesis in the glycogen-rich cells appears to be somewhat insensitive to cellular glycogen level, suggesting the absence or deficiency of such a feedback mechanism.

2087 TRANSFER AND RIBOSOMAL RIBONUCLEIC ACIDS IN BRAIN TUMORS. (E.) Viale, G. L. (Neurosurg. Clin., U. Genoa, Italy), H. Kroh, G. Grosso and E. Viale. *Neurosurg* 34(3): 446-447, 1971.

Methylation of transfer and ribosomal ribonucleic acids and methylase activity in human gliomas has been studied by means of infrared spectrophotometry. Transfer RNA of malignant gliomas presented a higher content of methylated nucleosides proportional to

the degree of malignancy and varied with the type of tumor, whereas ribosomal RNA did not show striking differences. The increased content of methylated nucleosides appeared to indicate increased non-tissue-specific tRNA methylase activity in all types of tumors.

2088 ASSAY OF tRNA METHYLASE ENZYMES IN STUDIES OF MALIGNANT TRANSFORMATION *IN VITRO*. (E.) Pillinger, D. J. (Christie Hosp., Manchester, England) and R. Wilkinson. *Life Sci* 10(5):241-249, 1971.

A normal clone of hamster kidney cells, a spontaneously transformed line of cells, and a line of cells derived from a cheek pouch tumor were cultured and treated with S-adenosyl-L-methionine (methyl- ^{14}C); the uptake of that agent by methyl deficient *E. coli* transfer RNA (tRNA) was used to measure the tRNA methylase activity in normal and neoplastic hamster cells. Supernatant fractions from the neoplastic cells incorporated twice as much of the labeled methyl group into the methyl deficient *E. coli* tRNA as did supernatants from normal cells. Cheek pouch tumor cells were more active than spontaneously transformed cells. tRNA methylase activity was found to be higher in kidney tissue from newborn hamsters than in kidney tissue from adults.

2089 SEROLOGIC SPECIFICITIES OF METHYLATED BASE IMMUNE SYSTEMS. (E.) Levine, L. (Grad. Dept. Biochem., Brandeis U., Waltham, Mass.), H. Van Vunakis and R. C. Gallo. *Biochemistry* 10(11):2009-2013, 1971.

New Zealand albino rabbits were immunized with 1.0 ml of complete Freund's adjuvant containing 5 mg of 1-methylguanosine, N²-methylguanosine, N²-dimethylguanosine, 7-methylguanosine or 5-methylcytidine injected once into the toepads and once i.m. each wk for 3 successive wks; the rabbits were bled from the ear 1, 2 and 3 wk subsequent to the final injection. The antibodies were directed toward the methyl group on the C-1 position of each of the methylated nucleoside-human serum albumin. Whereas the methylated guanosine immune systems were relatively easy to inhibit with the homologous nucleoside (50% inhibition ranging from 30-50 nmoles), this methylated cytosine immune system was more difficult to inhibit with its homologous nucleoside (2000 nmoles required for 50% inhibition). If the tRNAs of neoplastic tissue contain methylated bases which differ from normal tissues, the amount of these bases and the ratio of one base to another in biological fluids may be indicative of the presence and/or relative amounts of the abnormal growth.

2090 ALTERATIONS IN SPECIFIC TRANSFER RIBONUCLEIC ACIDS IN A SPECTRUM OF HEPATOMAS. (E.) Srinivasan, D. (Coll. Phys. Surg. Columbia U., New York, N.Y.), P. R. Srinivasan, D. Grunberger, I. B. Weinstein and H. P. Morris. *Biochemistry* 10(11):1966-1973, 1971.

The tRNAs for tyrosine, histidine, asparagine, and phenylalanine of five Morris hepatomas grown i.m. in the thigh muscle of male rats of the inbred ACI T² strain and the Buffalo strain were compared to the corresponding tRNAs from livers of normal rats of the same strains, sex and age. Tyrosyl-tRNA from hepatoma 3924A eluted at a higher salt concentration than that from the control rat liver; no difference was seen in hepatomas 9121, 3683F and 5123C from control profiles. Tyrosyl-, histidyl- and asparaginyl-tRNA eluted at a higher salt concentration from hepatoma 3924A, whereas the phenylalanyl-tRNA profile was identical with that of normal liver. The other hepatomas showed only altered phenylalanyl-tRNA profiles, which eluted earlier than the controls. The codon recognition properties of tyrosyl-tRNAs from Novikoff hepatoma, hepatomas 3924A and 9098, and normal rat liver were also examined. The normal tyrosine codons UAU and UAC were recognized by all of the tyrosyl-tRNAs with the greater response being shown to UAU and with no response to the chain terminator codons UAG and UAA. These results indicate that these tRNAs are not the same as the tyrosyl-tRNA nonsense suppressors of bacteria.

- 2091 THE TRANSFER RNA METHYLASES OF HUMAN LYMPHOCYTES: II. DELAYED INDUCTION BY PHA IN LYMPHOCYTES FROM PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. (E.) Riddick, D. H. (U. Virginia Med. Sch., Charlottesville) and R. C. Gallo. *Blood* 37(3):293-298, 1971.

When peripheral blood from patients with untreated chronic lymphocytic leukemia (CLL) was centrifuged and the lymphocytes were treated with phytohemagglutinin (PHA), the specific rate of transfer RNA (tRNA) methylases in lymphocytes treated with PHA for 120 hr was 5 times the rate of tRNA methylase in CLL lymphocytes not treated with PHA. In addition, the extent of tRNA methylation was 400% higher in PHA-stimulated CLL lymphocytes than in controls. Cells incubated in cultures without PHA were small mature lymphocytes, while PHA-stimulated cells showed 8.2% large transformed cells. Blastic transformation of CLL lymphocytes cultured with PHA proceeded at a slower pace than PHA-stimulated lymphocytes of normal subjects; CLL lymphocytes attained maximal transformation rates after 168 hr in culture with PHA, while PHA-treated lymphocytes of normal subjects reached maximal transformation rates after 40 hr in culture. Levels of tRNA methylase were similar in normal and CLL lymphocytes without PHA stimulation. The increase in the activity of tRNA methylase in PHA-stimulated CLL lymphocytes may be associated with enzymes which were not present prior to PHA treatment, suggesting that PHA induces quantitative and qualitative changes in tRNA methylase enzymes of CLL lymphocytes.

- 2092 CHROMOSOMAL ABERRATIONS AND THEIR RELATION TO MALIGNANCY IN MENINGOMAS: A MENINGIOMA WITH RING CHROMOSOMES. (E.) Mark, J. (Inst. Path., U. Lund, Sweden). *Acta Path Microbiol Scand* 79(2): 193-200, 1971.

Karyotype studies were carried out on cells from a benign human syncytical meningioma; tumor cells maintained *in vitro* were examined in 3 fixations made 5, 37 and 88 days after explanation of the tumor. In the first fixation, nearly 50% of the cells had the stemline number 42 with a minor second mode at stemline number 45. The stemline karyotype in this fixation contained a large ring chromosome; the ring was also seen in triploid and hypotetraploid cells in the first fixation. Seventy-five percent of cells, the stemline, possessed the ring chromosome while 25% of cells, the sideline population, lacked it. In the second fixation, the hypodiploid stemline found in fixation 1 had disappeared and was replaced by a 46-chromosome stemline; however, the hypodiploid sideline with chromosome number 45 persisted. The 45-chromosome sideline lacked a G chromosome in all 3 fixations. It was thought that the persistence of the sideline may have been a result of the persistence of a remnant of a stemline developed in the *in vivo* growth of the meningioma. Outgrowth of stroma cells may have been responsible for the shift in stemline characters.

- 2093 GENETIC PREDISPOSITION TO MELANOMA AND OTHER SKIN CANCERS IN AUSTRALIANS. (E.) Lane Brown, M. M. (Massachusetts Gen. Hosp., Boston), C. A. B. Sharpe, D. S. Macmillan and V. J. McGovern. *Med J Aust* 58(16):852-853, 1971.

A survey of 1,433 patients from the Sydney, Australia area with melanomatous cutaneous metastases, non-cutaneous cancer, basal cell carcinoma or squamous cell carcinoma was conducted to determine the prevalence of melanoma among Australians of Celtic ancestry. Celtic ancestry was ascertained by noting the surnames of patients in the survey. Persons of Celtic genetic heritage were disproportionately represented among patients with skin cancer, including melanoma. Fifty percent of the patients with melanomatous cutaneous metastases were of Celtic descent, as were 43% of the patients who had died from melanoma. Forty-eight percent of the patients with basal cell carcinoma were Celtic, and 47% of the patients with squamous cell carcinoma were Celtic. The percentages of persons with a Celtic background among those with skin cancer, including melanoma, was almost twice the figure obtained for persons of non-Celtic heritage.

- 2094 SOME PRELIMINARY OBSERVATIONS ON THE INFLUENCE OF GENETIC ADMIXTURE ON CANCER INCIDENCE IN AMERICAN NEGROES. (E.) Petrakis, N. L. (U. California Sch. Med., San Francisco). *Int J Cancer* 7(2):256-258, 1971.

A correlation was found between degree of admixture of white with American Negro genes and incidence of breast cancer. Genetic admixture was measured by observing the frequency of the Duffy Fy(a⁺) gene, which is present in white populations and absent in African Negroes (the frequency of the Duffy gene in the United States whites was taken as unity). Afri-

an Negroes with zero genetic admixture showed 9 cases of breast cancer/100,000 population; American Negroes with genetic admixtures of 0.106, 0.219 and 0.260 had breast cancer incidences of 38.5, 43.3 and 44.6 cases/100,000 population, resp. Whites had an incidence rate for breast cancer of 69 cases/100,000 population. No correlation was found between genetic admixture and cervical cancer, rectal cancer, lung cancer, stomach cancer, esophageal cancer or prostatic cancer.

95 A SPECIFIC COMMON CHROMOSOMAL PATHWAY FOR THE ORIGIN OF HUMAN MALIGNANCY: II. (E.) Minkler, J. L. (Lawrence Radiat. Lab., California, Livermore), J. W. Gofman and K. Tandy. *Brit J Cancer* 24(4):726-740, 1970.

The relationship of excess E16 chromosome and human cancer was studied in fresh cancer tissue obtained from surgical specimens on the basis of chromosome length and centromeric index. All cell lines studied only the E16 chromosome class showed a mean chromosome number per cell elevation with a mean E16 level 2.03 times the "corrected E16 expectation" *in vitro*; in 10 of 11 fresh cancers absolute E16 chromosome levels were significantly elevated, and "corrected expectation" figures showed significant E16 chromosome elevation.

96 HUMAN LEUKEMIA: GENETIC AND ENVIRONMENTAL CLUSTERS. (E.) Heath, C. W., Jr. (Natl. Communicable Dis. Ctr., Atlanta, Ga.). *Bibl Haemat* 649-653, 1970.

An instance of leukemia or lymphoma occurring in members of a sibship and an instance of lymphosarcoma arising in 4 persons associated with a herd of lymphosarcoma-affected dairy cattle are reported. In the sibship, 5 of 12 sibs had died of leukemia or lymphoma; there were 2 cases of chronic lymphocytic leukemia, 1 case of lymphocytic lymphoma, and 2 cases of reticulum cell sarcoma. Of the 4 surviving cows, all had low IgG immunoglobulin levels and decreased delayed hypersensitivity responses; 2 sibs had decreased lymphocyte transformation and increased lymphocytes in the bone marrow. The results suggest that the surviving sibs are in a pre-leukemic state. Four cases of lymphosarcoma occurring in a population of 200 living in the vicinity of a lymphosarcoma-affected dairy herd represented a significant increase over the expected lymphosarcoma incidence. The dairy herd in question consisted of 250 cows in which 1 case of lymphosarcoma had occurred per yr.

97 ENZYMIC MODIFICATION OF CHROMOSOMAL MACROMOLECULES: II. THE FORMATION OF HISTONE 3-METHYL-L-LYSINE BY A SOLUBLE CHROMATIN METHYLASE. (E.) Burdon, R. H. (Dept. Biochem., U. Glasgow, Scotland) and E. V. Garven. *Biochim Biophys Acta* 232(2):371-378, 1971.

Chromatin preparations from Krebs 2 ascites cells devoid of histone were incubated with methyl-labeled S-adenosyl-L-methionine and assayed for their ability to catalyze the transfer of methyl groups of protein; the resulting amino acids were analyzed by paper electrophoretic and chromatographic techniques to determine the nature of the product. Initially methyl uptake was low and then showed a dramatic increase with the addition of calf thymus histone at an optimal pH8. Methylation was reduced 96% when the reaction mixture was heat-treated at 100% for 5 min. Cytochrome c, ribonuclease, trypsin inhibitor, bovine serum albumin, lysozyme, γ -globulin, apoferritin, β -galactosidase, poly L-arginine or poly L-lysine had no effect on uptake and increasing concentrations of Mg^{+2} were somewhat inhibitory. No inhibition was noted in the presence of sodium formate, aminopterin or pyromycin. Only $1/3$ of the labeled product was associated with histone; the rest of the label appeared in an acid-insoluble protein as ϵ -N-trimethyl-L-lysine.

2098 LONG ACROCENTRIC MARKER CHROMOSOMES IN MALIGNANT EFFUSIONS AND SOLID TUMORS. (E.) Benedict, W. F. (Natl. Inst. Hlth, Bethesda, Md.), C. D. Brown and I. H. Porter. *New York J Med* 71(9):952-955, 1971.

Karyotype analysis of cells in effusions from 24 malignant tissue specimens, including breast carcinomas, cervical carcinoma and lung carcinoma, showed a long acrocentric marker chromosome in 75% of metaphases. Eleven of 18 solid tumors (61%), including osteogenic sarcoma, bronchogenic carcinoma, malignant lymphoma and transitional-cell carcinoma were found to have long acrocentric marker chromosomes (direct and short-term cultures).

2099 A HUMAN TISSUE CULTURE CELL LINE FROM A TRANSITIONAL CELL TUMOR OF THE URINARY BLADDER: GROWTH, CHROMOSOME PATTERN AND ULTRASTRUCTURE. (E.) Rigby, C. C. (St. Paul's Hosp., London, England) and L. M. Franks. *Brit J Cancer* 24(4):746-754, 1970.

The cytological behavior of urothelial neoplasms *in vitro* and *in vivo* was studied in cell cultures from 18 human bladder tumors. Three cell lines were maintained for 7 transfer generations; each had a fibroblastic morphology and a normal diploid karyotype, and a 4th line was maintained in continuous culture. In the primary and first subcultures the cells had a predominantly epithelial pattern with patches of fibroblast-like cells which disappeared in succeeding cultures. Nucleoli were large and usually single with foamy cytoplasm containing glycogen granules and few fat droplets. Cells from the 6th and 7th transfer generations used for heterotransplantation developed tumor nodules resembling the primary tumor in 3 of 15 hamsters inoculated after 21, 40 and 259 days resp. Chromosome analysis in the early stages of culture showed the presence of the stemline number and karyotype as was demonstrated in later transfer generations with a mode of 48 and 60% adherence to

a pattern in which there was an extra chromosome in Group C and in Group D, and only occasionally marker chromosomes.

- 2100 ENZYMIC MODIFICATION OF CHROMOSOMAL MACROMOLECULES: I. DNA AND PROTEIN METHYLATION IN MOUSE TUMOUR CELL CHROMATIN. (E.) Burdon, R. H. (Dept. Biochem., U. Glasgow, Scotland). *Biochim Biophys Acta* 232(2):358-370, 1971.

Chromatin preparations from Krebs 2 ascites cells were incubated with ^3H -methyl-labeled S-adenosyl-L-methionine at 37°, 23° C and at room temperature for varying times in preparation for chromatographic and electrophoretic analysis. Maximum level of label incorporation was obtained at 10-20 min at 37°; 40% of these methyl groups were rendered acid-soluble in hot 15% trichloroacetic acid. The addition of pancreatic deoxyribonuclease increased the label uptake into alkali-stable, acid precipitable material, while ribonuclease had no effect; snake venom diesterase augmented label incorporation and could be correlated with the loss of DNA from the chromatin fraction. Deoxyribonuclease produced maximal stimulation and caused all radioactivity to be alkali-stable and precipitable when heated at 100° for 5 min following treatment with 15% trichloroacetic acid. The bulk of the ^3H radioactivity chromatographed with a fraction almost corresponding to lysine. Examination of the hydrolysis products of the protein fraction incubated for 2 hr at 37° without deoxyribonuclease revealed ^3H radioactivity in regions corresponding to ϵ -N-methyl-L-lysine in addition to the ϵ -dimethyl- and ϵ -trimethyl- regions. Addition of homologous DNA increased the level of DNA methylation, whereas calf thymus DNA was less effective; no stimulatory effect was noted with the addition of bacterial DNA, which produced inhibitory effects in some cases. Methylation of DNA and protein showed an inverse proportion at 37°; at 23°, although the total label incorporation was not significantly different, the proportion incorporated into the protein was greater.

- 2101 A SPECIFIC COMMON CHROMOSOMAL PATHWAY FOR THE ORIGIN OF HUMAN MALIGNANCY: II. EVALUATION OF LONG-TERM HUMAN HAZARDS OF POTENTIAL ENVIRONMENTAL CARCINOGENS. (E.) Minkler, J. L. (Lawrence Radiat. Lab., U. California, Livermore), J. W. Gofman and R. K. Tandy. *Advances Biol Med Phys* 13:108-151, 1970.

Fresh cancer tissue from 11 patients with positively diagnosed malignant effusions or solid cancers, bone marrow from an untreated case of chronic granulocytic leukemia, and a suspension culture from Burkitt's lymphoma were studied for chromosome length and centromeric index. The only chromosome showing significant elevation or depression in all cell lines studied was E16; the elevation in mean number of chromosomes/cell was highly significant in every case, and averaged 3.10-fold for the entire group. All but one cell line showed a mean total number of chromosomes greater than the 46 chromosomes characteristic of normal cells,

and the E16 elevation was significantly and appreciably greater than that expected from the elevation in the total number/cell. Similar results were obtained in chromosome preparations made 2-20 hr after excision of fresh cancer tissue or withdrawal of the malignant effusion in 10 of the 11 biopsies studied; the 11th specimen revealed a value of 37.13 total chromosomes/cell; however, the E16 level, when compared to the total number, was significantly high. No other chromosome class showed consistent elevation or depression. Chronic granulocytic leukemia cells failed to show elevated numbers of E16 chromosomes. Chromosome numbers in cells from Burkitt's lymphoma were normal, and each cell showed a specific marker chromosome, the content of which is unknown.

- 2102 LIPOGRANULOMAS IN HUMAN LIVER BIOPSIES WITH FATTY CHANGE: A MORPHOLOGICAL, BIOCHEMICAL AND CLINICAL INVESTIGATION. (E.) Christoffersen, P. (Commun. Hosp. Copenhagen, Denmark), O. Braendstrup, E. Juhl and H. Poulsen. *Acta Path Microbiol Scand* 79(2):150-158, 1971.

Of 67 percutaneous human liver biopsies showing fatty change, 43 contained lipogranulomas presenting one of 3 typical features: some lipogranulomas consisted of a single nodule with a large extracellular vacuole surrounded by histiocytes, some consisted of a solitary nodule composed of histiocytes of which the majority were lipophages or lymphocytes, and others were multinodular structures composed of confluent nodules of both or either of the first 2 types. Lipogranulomas of the second type were thought to have developed from lipogranulomas of the first type. Ninety-eight percent of liver biopsies with lipogranulomas and 54% of those without lipogranulomas showed lytic necroses; 28% of lipogranulomatous biopsies contained acidophilic bodies, while none of the lipogranuloma-free biopsies contained acidophilic bodies. Kupffer cell proliferation was seen in all lipogranulomatous biopsies and by 21% of lipogranuloma-free biopsies. There was no significant difference between the 2 groups of biopsies regarding the incidence of portal fibrosis, bile duct proliferation, cholestasis, siderosis and content of lipofuscin. Biochemical tests showed that serum aspartate transaminase was higher in the group of biopsies with lipogranulomas than in the group of biopsies without lipogranulomas. Multinodular lipogranulomas were thought to be more likely to develop connective tissue in the liver parenchyma than single-nodular lipogranulomas, which often disappeared without serious complications.

- 2103 FINE STRUCTURE OF AN OAT CELL CARCINOMA OF THE LUNG ASSOCIATED WITH ECTOPIC ACTH SYNDROME. (E.) Corrin, B. (St. Thomas Hosp. Med. Sch., London, England) and M. McMillan. *Brit J Cancer* 24(4): 755-758, 1970.

Human pulmonary oat-cell carcinoma associated with ectopic adrenocorticotrophic hormone syndrome was studied electron-microscopically. The fine structure showed abundant free ribosomes and lack of inter-

cellular connections, with small dense cytoplasmic granules, identical to those of non-secretory oat-cell carcinomas. In this hormonally active tumor, the granules were more numerous, suggesting a secretory nature. The tumor produced a negative silver reaction. Common histogenesis for cells with this type of secretory granule cannot be claimed in view of their presence in mesothelioma.

04 ELECTRON MICROSCOPY OF GLYCOGEN IN MENINGO-
 GOTHelial MENINGIOMA. (E.) Koizumi, J.
 Arch. Med. Chiba U., Japan) and S. Minei. *Arch*
Stol Jap 32(4):347-354, 1970.

Three human meningotheial meningiomas were excised and prepared for electron microscopy; the tumor cells were found to contain glycogen in varying amounts. Glycogen was found in cytoplasmic granules which showed an affinity for lead staining. In some cases, glycogen granules occupied practically the entire cytoplasmic matrix; in other cases, glycogen granules were diffused throughout the cytoplasm and the processes, while in other cells no glycogen granules could be seen. Glycogen granules were both single and compound. Cell metabolism of a neoplastic character may have produced abnormal carbohydrate metabolism in certain of the cells, leading to the observed variation in the distribution of glycogen granules.

05 CARCINOMA OF THE PANCREAS, INFANTILE TYPE:
 A LIGHT AND ELECTRON MICROSCOPIC STUDY.
 Fable, W. J. (Med. Coll. Virginia, Richmond),
 J. S. Still and S. Kay. *Cancer* 27(3):667-673,
 1971.

Sections from an islet cell adenoma of the pancreas arising in a 4-yr-old girl were examined by electron microscopy; it was found that the tumor invaded the superior mesenteric vein and the wall of the transverse colon. Two patterns of cell growth were found in the tumor material: small cells growing in an acinar and cord-like pattern, and spindle and squamoid cells. Glycogen was found in the tumor cells. Ultrastructurally, the tumor was seen to contain uniform cells surrounding small lumina; the luminal surface of the cells had microvilli. The microscopic picture suggested that the tumor at hand originated in the duct cells and showed some differentiation in the direction of acinar cells.

06 ELECTRON MICROSCOPIC STUDY OF BASAL CELL
 CARCINOMA. (E.) Ishibashi, A. (Nihon U.
 Med., Tokyo, Japan), T. Kasuga and E. Tsuchiya.
Invest Derm 56(4):298-304, 1971.

Electron microscope inspection of samples from 3 basal cell carcinomas showed stromas consisting of granular and amorphous materials including glomerular masses; this material was seen in widened intercellular spaces as well as in stroma, and was thought to represent mucopolysaccharides revealed by metachromasia. Transparent bodies composed of

a glassy amorphous matter or of multiple tubular membranous structures were seen in the surfaces of plasma membranes; it was speculated that this amorphous material was related to metachromasia, perhaps reflecting secreting activity of the neoplastic cells. The cytoplasmic matrices of the tumors were found to contain cytolytic caverns filled with material of low electron density. Melanin granules undergoing digestion were seen in the neoplastic keratinocytes; premelanosome-like granules were also seen.

2107 ELECTRON MICROSCOPIC STUDIES OF THE TRANSMISSIBLE SARCOMA IN DOGS. (Rus.) Shubin, A. S. (Inst. Exp. and Clin. Oncol. Acad. Med. Sci. Moscow, U.S.S.R.) and V. I. Ponomar'kov. *Arkhl Patol* 33(3):38-42, 1971.

The morphology and ultrastructure of transmissible sarcoma (Sticker's tumor) was investigated in 5 dogs. The tumors consisted of large flattened cells with a light cytoplasm and a round nucleus. Papillary structures were noticed near the cell surface and an alveolar constitution within the deeper layers of the tumor was observed. Electron microscopy revealed small vacuoles within the cytoplasm; both vacuoles and cytoplasm exhibited fine fibrillar structures. The Golgi apparatus appeared to be scarce and was represented by a hypertrophic vesicular component. Unusual parallel rows of membrane complex-like formations were also noticed within the cytoplasm. The widening of some of these membranes led to the formation of vacuoles. The nature and possible relationship of these membranes to the Golgi apparatus or to the endoplasmic reticulum is discussed.

2108 THE TWO VARIETIES OF LYMPHOID TISSUE
 "RETICULOSARCOMAS", HISTIOCYTIC AND
 HISTIOBLASTIC TYPES. (E.) Mathe, G. (Hosp. Paul
 Brousse, Villejuif, France), R. Gerard-Marchant,
 J. L. Texier, J. R. Schlumberger, L. Berumen and
 M. Paintrand. *Brit J Cancer* 24(4):687-695, 1970.

Histological and cytological examinations were performed on 110 sections and smears of reticulosarcomas; this nosological entity was subdivided into 2 classes, histiocytic and histioblastic reticulosarcoma, on the basis of the examination. Histiocytic sarcomas often presented an intense network of reticulin with 60% of histiocytic sarcomas and only 4% of histioblastic sarcomas containing reticulin. Histioblastosarcoma was found to be more frequent than histiocytosarcoma; 74 cases of the former condition and 36 of the latter were found in this group. Histioblastosarcoma was especially frequent among men and comprised 70% of male reticulosarcomas and 30% of female reticulosarcomas. During the development of these conditions, 27.7% of histiocytosarcoma patients and 2.6% of histioblastosarcoma patients showed cutaneous manifestations. Seventeen percent of histioblastosarcoma cases developed into leukemia, while none of the histiocytosarcoma cases developed into leukemia.

- 2109 PRELIMINARY OBSERVATIONS ON THE HISTOCHEMISTRY OF THE CELL SURFACE OF CARCINOMA OF THE CERVIX. (E.) Bradbury, S. (Dept. Human Anat., U. Oxford, England), G. Wiernik, E. A. Williams and R. H. Cowdell. *Brit J Cancer* 24(4):741-745, 1970.

Surface histochemistry of carcinoma of the uterine cervix and its response to radiation treatment was studied in squamous cell carcinoma human biopsies and one adenocarcinoma. The cell coat and intercellular matrix of the cervical carcinoma cell was rich in hyaluronic acid and did not contain any appreciable number of sulfate groups but was positive for sialic acid. The mucosubstances of the cell coat and intercellular matrix formula may be written C(G) mucosubstance; B 3.5; A 2.5 (0.6 M $MgCl_2$); T; S. Histochemical differences in the composition of the cell coat and intercellular matrix were not shown when comparing normal, carcinomatous and irradiated carcinomatous cervical tissue. It is obvious from these studies that this differs markedly from the trophoblast.

- 2110 THE STORAGE CELLS OF CHRONIC MYELOGENOUS LEUKEMIA. (E.) Lee, R. E. (U. Pittsburgh Sch. Med., Pa.) and L. D. Ellis. *Lab Invest* 24(4):261-264, 1971.

Bone marrow from patients with Gaucher's disease and chronic myelogenous leukemia was aspirated and prepared for electron microscopy. Leukemic cells were similar to Gaucher's disease cells under low magnification; however, under high magnification, the cytoplasmic sacs in the leukemic cells contained round, dense deposits peculiar to leukemic cells. Other linear deposits in the leukemic cells had a periodicity of 80-100 Å, and were composed of 2-20 parallel units. Gaucher cells contained cytoplasmic sacs comprising twisted tubes 300-400 Å in diameter with fibrillar walls. Ferritin particles were common in the storage cells of both leukemia and Gaucher's disease patients. Stored material in macrophage cells of leukemic patients was thought not to be cerebroside, or to be cerebroside in a different form from that in which it was found in cells from patients with Gaucher's disease.

- 2111 COMMENTS ON THE HISTOGENESIS OF MEDULLARY CARCINOMA OF THE THYROID WITH AMYLOID STROMA: REPORT OF 5 INSTANCES WITH ELECTRONMICROSCOPIC STUDY IN 2 CASES. (Fr.) Benatre, A. (C.H.R. Bretonneau, Tours, France), C. David and P. Jobard. *Arch Anat Path* 19(1):5-17, 1971.

Light microscopy of 5 medullary thyroid carcinomas with amyloid stroma revealed that initially the tumors were multicentric and perifollicular, with the tumor proliferation infiltrating the acini. Appearance of amyloid substance was relatively late and was completely lacking in more recent tumor nodules. Two cellular types were demonstrated by

electron microscopy: some rich in secretory granules and others with marked dilatation of cavities in the endoplasmic reticulum. Fluorescent and PAS studies suggest that after a secretory stage, tumor cells elaborate a pre-amyloid substance whose accumulation leads to depletion of cells. Since the parafollicular cells, which are precursors of medullary carcinoma are derived from the neural crest, it appears that cells other than mesenchymal cells can synthesize amyloid.

- 2112 BIOLOGICAL AND MORPHOLOGICAL CHARACTERISTICS OF MAMMARY TUMORS IN GR MICE. (E.) Van N. R. (Netherlands Cancer Inst., Amsterdam) and A. Dux. *J Nat Cancer Inst* 46(4):885-897, 1971.

The hormone dependency and growth of mammary tumors arising in GR mice was investigated in mice in 4 experimental categories: virgin mice, females bearing 1, 4 or 8 pituitary isografts in the kidney, ovariectomized mice treated with estrone, and force-bred mice. In addition, the progress of mammary tumors transplanted onto animals in these categories was observed. Mice in all groups developed mammary tumors with great frequency (84-100% incidence). Tumors appeared earlier in mice with pituitary grafts than in virgin mice; mice with 4 or 8 grafts developed tumors at an average age of 256-261 days, while mice with 1 graft developed tumors at an average age of 302 days. Ovariectomized mice treated with estrone also developed tumors earlier than did virgins; for bred mice developed tumors in 100% of the cases after the shortest latency (88 days of age) recorded for any group. Most tumors in the force-bred group were small and regressed after a few days. All tumors in virgin mice grew progressively; however, tumors in force-bred mice regressed after cessation of breeding and 3 of 10 tumors arising in mice with 1 pituitary graft regressed following ovariectomy and removal of the graft. Mammary tumors derived from virgin mice were transplanted to estrone-treated, estrone-and-progesterone-treated, and untreated mice with the result that 9 of 10 transplanted tumors grew in all mice, and were considered hormone-independent. Tumors from mice with 1 pituitary isograft were found on transplantation to be hormone-dependent, and tumors from ovariectomized mice treated with estrone were hormone-responsive and grew more efficiently in estrone-treated mice than in untreated castrated mice. Tumors derived from force-bred mice were hormone-dependent in 11 cases and were hormone-responsive in 2 cases. Most tumors arising in force-bred mice were classified morphologically as mammary tumor type P (pregnancy dependent), while most tumors arising in other groups were mammary adenocarcinomas types A and B. So-called "pale cell carcinomas" were also seen and were especially common in mice with pituitary isografts.

- 2113 BANDED STRUCTURES IN THE CONNECTIVE TISSUE OF LYMPHOMAS, LYMPHADENITIS, AND THYMOMAS (E.) Mollo, F. (Fac. Med. Surg., Turin, Italy) and G. Monga. *Virchow Arch Zellpath* 7(4):356-366, 1971.

Human lymph node and thymic tumors were examined electron microscopically; the thymic tumors were

granulomatous thymomas, and the lymph nodes were prepared from patients with Hodgkin's disease (24 specimens), reticulum cell sarcoma (6 specimens), lymphosarcomas (7 specimens), chronic lymphoid leukemia (3 specimens), acute leukemia (1 specimen) and nonspecific lymphadenitides (5 specimens). Distinctive banded structures in the connective tissue of lymph nodes were observed in 20 of the Hodgkin's disease cases, in 2 of the reticulum cell sarcoma cases, in 4 of the lymphosarcoma cases, in 1 of the nonspecific lymphadenitides and in both of the cases of granulomatous thymoma. Banded structures were prominent in Hodgkin's disease and thymoma specimens, and rarer in the other specimens. These structures were especially but not exclusively found in specimens showing fibrous or hyaline changes under the light microscope. Intercellular substances were sometimes seen in the specimens. Banded structures were usually ordered in a regular rhythmic manner, with a period of about 1000 Å; they were composed of interfibrillar ground substance and were sometimes associated with round areas of a similar dense ground material. The dense substance of the dark bands was similar to basement membrane material. In some cases, bands were abundant in the connective tissue surrounding small blood vessels. Collagen fibers, usually arranged in the conventional periodic pattern, and thick fibrillar structures were also seen.

- 2114 PROLIFERATION OF MICROBODIES AND SYNTHESIS OF CATALASE IN RAT LIVER: INDUCTION IN TUMOR-BEARING HOST BY CPIB. (E.) Reddy, J. (U. Kansas Med. Ctr., Kansas City) and D. Svoboda. *Amer J Path* 63(1):99-106, 1971.

Weanling male rats were given implants of an aflatoxin-induced hepatoma, an ethionine-induced hepatoma or an actinomycin-induced mesothelioma followed, after 8-12 wk of tumor growth, by a course of dietary ethyl- α -p-chlorophenoxyisobutyrate (clofibrate, CPIB). Liver catalase activity in animals bearing transplanted tumors was lower than in normals; catalase activity in normals measured 40 U/mg protein (mean) and catalase activity in animals bearing one or another of the 3 tumors used ranged from 13-19 U/mg protein. In rats given CPIB following tumor transplantation, catalase values increased and exceeded control values; catalase in CPIB-treated tumor-bearing rats ranged from 59-70 U/mg protein. Determination of the quantity of catalase protein in CPIB-treated tumor-bearing rats and in untreated tumor-bearing rats indicated that the content of catalase protein in the livers of normal rats and of tumor-bearing rats was significantly increased by treatment with CPIB.

- 2115 ULTRASTRUCTURAL STUDIES ON MONOCYTIC LEUKAEMIA. (E.) Freeman, A. I. (Roswell Park Mem. Inst., Buffalo, N.Y.) and L. J. Journey. *Brit J Haemat* 20(2):225-231, 1971.

Bone marrow cells from 7 patients with monocytic leukemia (Schilling type) or myelo-monocytic leukemia (Naegeli type) were examined under the electron microscope; monoblasts and myeloblasts were compared.

While myeloblasts showed regular rounded nuclei, monoblast nuclei were irregular with deep indentations or folds; bridges and blebs were common in monoblasts, rare or absent in myeloblasts. Chromatin condensation along the nuclear margin was seen in both cell types; however, myeloblast nuclei possessed nucleoli more often than did the nuclei of monocytes. Golgi apparatus was commonly seen in monoblasts, rarely in myeloblasts; Golgi bodies were often found in the indentations in the monoblast nucleus. Cytoplasmic volume was moderate in monoblasts and scanty in myeloblasts, as were fibrillar formations. Mitochondria, which were common in monoblasts, were scattered throughout the cytoplasm; mitochondria were uncommon in myeloblasts and, when found, were located in the polar areas of the cells. Cytoplasmic vesicles, vacuoles and pseudopodia, common or moderate in monoblasts, were rare or absent in myeloblasts.

- 2116 SPREAD OF TESTICULAR TUMOURS. (E.) Van Der Werf-Messing, B. (Rotterdam Radiother. Inst., Netherlands). *Clin Radiol* 22(1):125-132, 1971.

Of 279 cases of testicular tumors surveyed, including seminoma, malignant teratoma intermediate (MTI), MTI with seminoma (MTI/S), and malignant trophoblastic teratoma (MTT), seminoma showed the best survival rate (79% of patients were surviving at 5 yr after radiation therapy), and MTT showed the worst survival rate (no 5-yr survivors). Metastases were least prevalent in cases of seminoma (36% of cases had metastases), and most prevalent in MTT (100% of cases with metastases); seminoma usually metastasized to the lumbar glands, while MTT usually metastasized to other glands and/or to the intra-thoracic region (lung parenchyma or mediastinum). Lumbar recurrence in patients surviving 2 yr or more was found to be more frequent after orthovoltage radiation than after supervoltage radiation. Most patients with intra-thoracic lesions also showed hilar involvement, whatever the nature of their primary tumor. There was also a close relationship between the incidence of pulmonary lesions and lumbar metastases in all histological types of testicular tumors; liver metastases were also correlated with lumbar involvement. Seminoma was found to be the least aggressive condition and showed a comparatively slow rate of spread and high sensitivity to radiation therapy. MTT metastasized very rapidly and was relatively insensitive to radiation.

- 2117 ASSOCIATION OF PULMONARY TUBERCULOSIS AND CARCINOMA OF THE LUNG. (E.) Kreus, K-E. (U. Central Hosp., Helsinki, Finland), M. Hakama and E. Saxen. *Scand J Resp Dis* 51(4):276-289, 1971.

Of 6436 tuberculosis patients registered in Finland in 1958, 124 were diagnosed as having lung cancer between 1958-1963. Of 111 of these cases, there were 41 instances of misdiagnosed tuberculosis and 3 cases of misdiagnosed cancer, leaving 67 confirmed cases of lung cancer coincident with tuberculosis. In 57% of the confirmed cases, the lung cancer was epidermoid, and in 25% the cancer was either small cell or undifferentiated. Fifteen cancer patients

without tuberculosis and 20 cancer patients with tuberculosis showed roentgenographic signs of bronchial localization, including obstructive pneumonitis and atelectasis. In 19 patients with both cancer and tuberculosis, a unilateral change in the hilum was observed; this condition was seen in only 3 patients without tuberculosis. In 12 of 37 cases of unilateral tuberculosis the carcinoma was located in the region of the tuberculous lobe, indicating that the disease process does not determine the localization of the carcinoma. In more than half the cases of tuberculosis and lung cancer, the interval between diagnosis of tuberculosis and diagnosis of cancer was more than 3 years. The expected number of cases of lung cancer varied between 24 and 29, depending on the assumed risk of tuberculosis mortality, indicating that the risk of developing lung cancer among tuberculosis patients is higher than in the normal population. All nontubercular cancer patients, and at least 55 of the 67 tubercular cancer patients, were found to be heavy cigarette smokers.

- 2118 TUMOUR GROWTH IN NEMATODE-INFECTED ANIMALS.
(E.) Keller, R. (Dept. Derm., U. Zürich, Switzerland), B. Ogilvie and E. Simpson. *Lancet* 1(7701):678-680, 1971.

Female A-strain mice were infected with the nematode *Nippostrongylus brasiliensis* simultaneously with, 7 days after, or 7 days prior to inoculation with spontaneous murine mammary adenocarcinoma cells. Nematode-infected mice showed depressed tumor growth compared to uninfected mice; 30 days after inoculation of tumor cells, the mean tumor wt in nematode-infected mice ranged from 1.4-2.8 g, while the mean tumor wt in inoculated animals not infected with nematode was 4.7-5.2 g. Antilymphocyte serum did not increase the rate of tumor growth in uninfected mice, but it did prevent the inhibitory action of the nematode on tumor growth in infected mice. Osborne-Mendel rats were infected with nematode, and tumor cells (Walker 256 sarcoma) were injected on the same day or 5, 10 or 30 days later. Nematode infection did not affect the growth of tumors in rats infected on the same day that they were inoculated with tumor cells; tumor growth was inhibited 100% in rats inoculated on day 5 after parasite infection, and tumor growth was enhanced in rats inoculated 10 or 30 days postinfection. The enhancing effect could be transferred with antiserum from rats infected with the nematode only, suggesting that the tumor and the parasite have a common antigen.

- 2119 A SPECIFIC TYPE OF ORGANISM CULTIVATED FROM MALIGNANCY: BACTERIOLOGY AND PROPOSED CLASSIFICATION. (E.) Livingston, V. W. C. (U. San Diego, Calif.) and E. Alexander-Jackson. *Ann NY Acad Sci* 174(2):636-654, 1970.

The morphological and physiological characteristics of a cancer isolate were investigated, described and classified. The organisms were intermittently acid-fast and gram-variable, with rod forms predominantly

gram-positive and the L-forms gram-negative. Sensitivity was usually shown toward tetracycline, kanamycin, ampicillin, cephalothin, furacin and oleandomycin; however, isolates from the very ill were insensitive to these and resistance to penicillin, sulfa drugs, polymixin B, bacitracin and mycostatin was common; growth was inhibited by *Listeria* polyvalent O and mycoplasma antisera. The organisms are classified as: Order: *Actinomycetales*, Family: *Progenitoraceae*, Genus: *Cryptocides*, Species: *Cryptocides tumefaciens*, *Cryptocides sclerodermatis*, *Cryptocides wilsonii*, Variants: *hominis*, *rodentii*, *avii*, etc. They were able to grow aerobically, microaerophilically or anaerobically at 37° C and at room temperature, with acid production occurring from glucose and liquefaction of gelatin occurring slowly. A characteristic colony type on agar appeared as a "fried egg" and had the ability to invade both the cytoplasm and nucleus of vulnerable host cells or to remain in a latent non-invasive globoid or cyst form in the blood or other tissues in the presence of adequate body defenses.

- 2120 TOXIC FRACTIONS OBTAINED FROM TUMOR ISOLATES AND RELATED CLINICAL IMPLICATIONS.
(E.) Livingston, A. M. (U. San Diego, Calif.), V. W. C. Livingston and E. Alexander-Jackson. *Ann NY Acad Sci* 174(2):675-689, 1970.

The pathogenic effects of a microorganism belonging to the order *Actinomycetales* and the genus *Cryptocides* on HeLa cells in tissue culture has been studied utilizing various culture media and microscopic techniques. Inoculation of the whole culture in broth, even in relatively small doses, led to the death of the tissue culture. Cultures grown in the dark at room temperature yielded a dark red-brown zone of pigmentation. Yields of similar reddish-brown pigmented material were isolated from the urine of tumor-bearing patients in increasing amounts as the patient became terminally ill, and confirmatory cultures made from urine and blood of the same patients revealed the same pigmented material on extraction compared to the absence of such material in controls. In a strain of mice with known pulmonary tumor response, the incidence of pulmonary tumor was 20% among controls compared to 50.6% among mice receiving extract of a broth blood culture from a terminal breast cancer patient and 40% and 28% in 2 groups receiving an extract of urine from a terminal cancer patient. More selective methods of extraction and increased purification of the material are indicated to determine further the toxicity of the observed fractions.

- 2121 EXPERIMENTS WITH MAMMALIAN TUMOR ISOLATES.
(E.) Diller, I. C. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.) and A. J. Donnelly. *Ann NY Acad Sci* 174(2):655-674, 1970.

Isolation of pleomorphic organisms from blood and neoplasms of male and female mice of several different strains of known tumor incidence (C3H/HeN1cr, C57BL/6JN1cr, C58, ICR/Ha and ICR/albino) was attempted, and the effect of inoculation of such isolates into mice was studied. Of 100 randombred ICR/Ha mic

whose blood was sampled for the presence of organisms, 56 developed spontaneous tumors, and 49 of these yielded organisms from the blood at the time of death. Of the 44 non-tumor-bearing mice, 37 were negative throughout the study and the remaining 7 died of causes unrelated to cancer. Only 2 of the mice that produced tumors failed to yield the organism either from blood or tumor tissue. In male mice of the same strain, 19% tumor incidence was detected with an average of 14% positive findings in blood at death or sacrifice, while strain C58 mice showed an incidence of 95% lymphatic leukemia among both male and female animals with positive blood findings for organisms at 76% and 88%, resp. In C3H/HeNIcr and C57BL/6JNIcr strain female mice tumor incidence was 95% and 32.6%, resp., compared to 34% and 16%, resp., among males, while the occurrence of organisms in blood was 81% and 30% among females and 30% and 21% among males. The predominant forms of the organisms were coccoids and rods of various sizes, globoids, motile forms, mycelial forms and granules, some of which were filter-passing. All cultures reverted to the coccoid stage unless they were subcultured at frequent intervals; under phase microscopy, the coccoid forms were seen to elongate to form rods. *In vitro* inoculation into freshly isolated mouse embryo cells revealed intracytoplasmic organisms on the second day post-inoculation with penetration of the nucleus by 48 hr while *in vivo* inoculation into mice resulted in survival from 24 hr to 1 wk with resultant abscess formation, cellular breakdown and tissue necrosis. Inoculation of 50 ICR/albino mice under 72 hr of age with the S-180 organism resulted in tumors in 44% of the animals compared to 0% in controls. Since the pleomorphic acid-fast organisms can be cultured so consistently from malignant tissue, their presence may be related to the neoplasias.

2122 FOLLICULAR LYMPHOMA OF THE SPLEEN IN PATIENTS WITH HEPATOSPLENIC SCHISTOSOMIASIS MANSONI. (E.) Andrade, Z. A. (U. Bahia Sch. Med., Salvador, Brazil) and W. N. Abreu. *Amer J Trop Med Hyg* 20(2):237-243, 1971.

In a series of 863 patients with hepatosplenic schistosomiasis mansoni, 8 patients were found to have follicular lymphoma of the spleen. The spleens of all patients were markedly enlarged; numerous small rounded whitish nodules were usually found in the splenic pulp. Lymph nodes were enlarged in 7 of the cases of follicular lymphoma. Clinical histories of patients with follicular lymphoma were similar to the histories of patients with hepatosplenic schistosomiasis mansoni. In 1 patient, a reticulosarcoma developed as a supraclavicular mass. Splenic changes caused by schistosomiasis appears to predispose to follicular lymphoma.

2123 AMEBIC GRANULOMA AND ITS RELATIONSHIP TO CANCER OF THE CECUM. (E.) Camacho, E. (Fac. Med. U. Guadalajara, Jalisco, Mexico). *Dis Colon Rectum* 14(1):12-16, 1971.

Forty Mexican patients (23 males and 17 females) with amebic granuloma of the cecum and 20 patients (12 males and 8 females) with adenocarcinoma of the

cecum were surveyed. Twenty-three of the 40 cecal granuloma patients had granulomas in the transverse colon and sigmoid as well as in the cecum. Clinical symptoms of amebic cecal granulomas and cecal adenocarcinomas were similar, and it was thought that cecal granuloma may be a precancerous condition.

2124 MORPHOLOGICAL, BIOLOGICAL, AND IMMUNOLOGICAL STUDIES ON ISOLATES FROM TUMORS AND LEUKEMIC BLOODS. (E.) Seibert, F. B. (VA Ctr., Bay Pines, Fla.), F. M. Feldmann, R. L. Davis and I. S. Richmond. *Ann NY Acad Sci* 174(2):690-728, 1970.

Tissue from human tumors and blood from leukemic patients were examined for the presence of bacteria. Isolates from the tumors and leukemic blood older than 2 days showed marked pleomorphism and variability in staining capacity. With time these organisms became more acid-fast and repeated growth on 10% glycerol agar increased the amount of acid-fast bacteria in 2 strains. Electron microscopic examination revealed extremely heavy cell walls with at least 1 strain showing external processes resembling flagella. RBC in whole blood from a preleukemic patient incubated with isolates from leukemic patients were bombarded by bacteria, which resulted in their disintegration, and the white blood cells became engorged with the bacteria and were agglutinated. When plasma which contained freely moving bacteria was added to sterile plasma, agglutination occurred rapidly in contrast to the lack of agglutination when added to sterile normal human serum. Leukemic blood containing acid-fast particulate antigen particles reacted strongly and specifically with an antiglobulin to an organism isolated from a human breast adenocarcinoma and which cross-reacted with several antibodies to other organisms studied. Tumor tissues from ICR/albino mice that had developed tumors following injection of organisms also showed the presence of acid-fast particles which fluoresced when the tissues were treated with the labeled antiglobulin made to the organism injected.

2125 COMPARISONS BETWEEN MYCOBACTERIA AND ISOLATES FROM TUMORS AND LEUKEMIC BLOODS. (E.) Dunbar, F. P. (Trudeau Inst., Saranac Lake, N. Y.), E. Howard and R. Cacciatore. *Ann NY Acad Sci* 174(2):872-876, 1970.

Organisms which had not been identified as members of a single species ("unnamed strains") were isolated from a variety of sources including blood of leukemia, carcinoma and polycythemia patients, the blood of a sarcoma-bearing rat, breast tissue from a mouse possessing the Bittner factor, and saliva from a normal individual. The isolated organisms were grown in various media and subjected to testing to determine whether they were mycobacteria. Only 1 of 15 unnamed strains grew on agar or Lowenstein-Jensen medium when inoculated in the media in amounts of 0.001 mg; mycobacteria, in contrast, grew in these media almost without exception. When media were inoculated with larger amounts of unnamed factors, 26 of 35 unnamed strains produced growth. After repeated subcultures,

the unnamed strains were tested for susceptibility to 9 antimicrobial agents including streptomycin (33 of 38 cultures were susceptible), penicillin (34 of 38 strains were susceptible), gantrisin (20 of 38 strains were susceptible) and erythromycin (33 of 38 strains were susceptible). The unnamed strains were more susceptible to streptomycin and penicillin than were mycobacteria. Unnamed organisms did not reveal the acid-fast properties of mycobacteria, and were more motile than mycobacteria; furthermore, unnamed strains were more susceptible to drugs than was usual for mycobacteria.

- 2126 THE THYMUS GLANDS AND LYMPHOSARCOMA IN THE PIKE, *ESOX LUCIUS* L. (PISCES; ESOCIDAE) IN IRELAND. (E.) Mulcahy, M. F. (Dept. Zool., U. Coll., Cork, Ireland). *Bibl Haemat* 36:600-609, 1970.

Irish pike (*Esox lucius*) bearing spontaneous lymphosarcoma and pikes injected with tumor homogenates prepared from lymphosarcomatous pike were killed and their thymuses were examined. Of 11 lymphosarcomatous pike, 4 had thymic tumors and 7 had grossly normal thymuses. In thymic tumors, the neoplasms had replaced the thymus, and had invaded adjacent muscle tissue. In 5 lymphosarcomatous pike, the thymus was involuted. The most frequently involved sites in a series of 65 pike with lymphosarcoma were the upper and lower jaws, trunk, and thymus. Two pike were given injections of tumor homogenate from lymphosarcomatous pike; 56 days later, the thymus of 1 of the pike showed some distortion of its normal structure, and the other pike developed a lower jaw tumor with marked change in the thymus involving abnormal proliferation of lymphoid cells.

- 2127 ON THE STATE OF DEVELOPMENT OF THE RUDIMENTS OF THE MAMMARY GLANDS AND TEATS IN THE NEW-BORN MICE BELONGING TO 5 SELECTED LINES RAISED IN THE PARIS RADIUM HOSPITAL. (Fr.) Raynaud, A. (Inst. Pasteur, Paris, France), J. Raynaud, N. Dobrovolskaia, G. Rudali, N. Adamoff and J. Defoort. *Bull Cancer* 57(4):447-476, 1970.

Of 5 mouse lines maintained in the Paris Radium Hospital, 2 developed frequent spontaneous mammary carcinomas; one showed a less pronounced tendency to develop carcinoma, and 2 lines did not develop spontaneous mammary carcinomas. In the 2 lines which did not develop spontaneous mammary carcinomas, a large percentage of the male rats examined lacked mammary rudiments, probably as a result of testosterone secretion *in utero*. The highest incidence of mammary rudiments among male rats was seen in those lines having a strong tendency to develop mammary carcinomas. In the low-cancer lines, rudimentary mammae seldom remained connected with epidermis, whereas in the high-carcinoma incidence lines, mammary rudiments sometimes were attached to the epidermis. In female rats, elevated mammary rudiments were seen in rats from the high-cancer incidence lines and in the line with a lesser tendency to develop cancer.

- 2128 STUDIES ON THE RELATIONSHIP BETWEEN LYMPHOCYTOSIS AND BOVINE LEUKOSIS. (E.) Abt, D. A. (Sch. Vetr. Med., U. Pennsylvania, Philadelphia) R. R. Marshak, H. W. Kulp and R. J. Pollock, Jr. *Bibl Haemat* 36:527-536, 1970.

Cattle herds having a single member with leukosis and herds having several members with leukosis were surveyed for incidence of lymphocytosis; of 5,373 cows whose blood was sampled, 376 had persistent lymphocytosis, representing a lymphocytosis rate of 7%. In these herds, there were 147 cases of confirmed leukosis of which at least 42 occurred in animals identified as having persistent lymphocytosis prior to the onset of symptoms of leukosis. In 24 cattle herds ostensibly without leukosis, 174 animals were found to have lymphocytosis (4.2%). Studies of familial aggregations of lymphocytosis indicated that while the offspring of a particular animal generally have similar levels of absolute lymphocyte counts in a given herd, they may show different levels in other herds. In 1 herd, the offspring of a particular bull had elevated lymphocyte counts, while that bull's offspring residing in other herds had normal lymphocyte levels.

- 2129 PROGRESS ON TRANSMISSION OF BOVINE LYMPHOSARCOMA. (E.) Olson, C. (Dept. Vetr. Sci., U. Wisconsin, Madison), L. D. Miller, J. M. Miller and K. G. Gillette. *Bibl Haemat* 36:476-492, 1970.

In 45 cows with lymphosarcoma, lymph nodes of the pelvic region were involved in 30 cases, and tumors in the heart were found in 30 cases; the abomasum was invaded by tumor in 24 cases. In herd studies of cattle with lymphosarcoma, lymphocytosis was often but not always associated with lymphosarcoma and frequently followed inoculation of cattle with tumor cells. In cattle injected with antigenic tumor lymph nodes, signs of a mild anaphylactic reaction were observed in 2 of 5 cases. Attempts to transmit lymphosarcoma by means of tumor cell suspensions at various ages and following X-irradiation were generally unsuccessful. An increase of lymphocyte nuclear projections was found regularly in lymphosarcomatous cattle and in cows with lymphocytosis. C-type particles were found in the majority of lymphosarcomatous cattle in 1 experiment; calves inoculated with lymphosarcoma material also showed C-type particles. It was not clear if the C-type particles were viruses or if they were causally related to the development of lymphosarcoma. Lymphocytosis was found to be more common and C-type particles were more often observed in cattle of a relatively advanced age.

- 2130 STUDIES ON LYMPHOCYTOSIS IN REGIONS OF HIGH AND LOW INCIDENCES OF BOVINE LEUKOSIS AND BABESIOSIS. (E.) Hugoson, G. (Natl. Vetr. Inst., Stockholm, Sweden). *Bibl Haemat* 36:537-543, 1970.

Hematological examination of Swedish cattle herds revealed that within a region of high bovine leukosis incidence the frequency of lymphocytosis was

higher than in regions of low leukosis incidence, the frequencies of leukosis in high and low lymphocytosis areas being 16.8 and 0.7%, resp. In the high leukosis region, the frequency of lymphocytosis in herds without a collective history of leukosis was 14.3%, while the frequency of lymphocytosis in herds with a history of leukosis was 19.4%. Herds with a single case of leukosis and herds with 2 or more cases of leukosis (multiple-case herds) showed similar frequencies of lymphocytosis. No cases of babesiosis, and no vaccinations against babesiosis, were found in cattle herds in an area of low leukosis incidence. The frequency of lymphocytosis in animals in herds vaccinated against babesiosis was lower than the frequency of lymphocytosis among cattle in herds without a babesiosis history and lower than that in unvaccinated herds in which babesiosis had occurred; however these differences were not statistically significant.

2131 CANINE MAST CELL LEUKEMIA. (E.) Post, J. E. (New York St. Vetr. Coll., Cornell U., Ithaca), F. Noronha and C. G. Rickard. *Bibl Haemat* 36:425-429, 1970.

Mast cell leukemias arising in Beagle dogs were transmitted through 15 generations by serial transfer of viable cells; during these passages, the latent period for mast cell tumor appearance decreased from 27-28 days to 6-8 days. Cell-free transmission of the tumor was not successful until the 8th passage, after which cell-free transmission was usually successful. In an additional 24 passages of the tumor through 24 generations, tumor transmission with cells was successful in 93 of 114 inoculated puppies. While adult dogs resisted tumor induction, dogs as old as 3 months developed tumors upon inoculation with fresh tumor cells. Cell-free transmission of mast cell leukemias was successful in 65 of 171 puppies; cell-free ascitic or pleural fluid and bone marrow produced higher incidences of tumors than plasma or tissue culture fluid. Transmission of tumor with ultrafiltrates produced few tumors. Mast cell leukemia induced by cellular or cell-free filtrates were similar to the spontaneous disease from which the inducing preparations were derived. C-type virus particles were found in tumor cells, but they were rare.

2132 SERIAL CELLULAR TRANSMISSION OF CANINE LYMPHOMA. (E.) Moldovanu, G. (Sloan Lettering Inst. Cancer Res., New York, N. Y.). *Bibl Haemat* 36:416-424, 1970.

Canine lymphosarcoma was passed through 15 transplant generations of mongrel dogs that had been irradiated (100 r) shortly after birth by two s.c. inoculations of lymphosarcoma cells (10^5) in the nape of the neck; inoculation was usually followed by the development of a local lymphoid tumor within 9-19 days which spread to bone marrow, liver, lungs and kidneys. When lymphosarcoma cells were injected into beagle dogs, lymphosarcomas failed to develop for 5 months, at which time 1 dog died with generalized visceral lymphoma. Another beagle died at 7 months with a large lymphosarcoma, and a third showed a small

regressing tumor. In subsequent transplant generations of beagles, local tumors remained comparatively small, thymuses were enlarged and infiltrated by lymphosarcoma, and metastases were found in brain and cerebellum. Lymphosarcoma cells from beagles were injected into irradiated adult guinea pigs, and 7 of 9 animals developed fibrosarcoma at the injection site. The tumor material from the guinea pigs produced lymphosarcoma in 1 puppy.

2133 PROSPECTIVE STUDY OF DOG BITE AND CHILDHOOD CANCER. (E.) Norris, F. D. (California St. Dept. Publ. Hlth., Berkeley), E. W. Jackson and E. Aaron. *Cancer Res* 31(4):383-386, 1971.

The number of deaths from leukemia and lymphoma among 49,239 children bitten by dogs in the Los Angeles area was less than the expected number of leukemia-lymphoma deaths when the time elapsed between bite and death was less than 4 yr. When the interval between bite and leukemia-lymphoma death was 4 or more yr, there were 5 deaths observed compared to 1.67 expected among children aged 10-14-yr-old. Standardized leukemia-lymphoma mortality ratios for the 10-14-yr-old age group rose about 3-fold following an interval of 4 or more yr after the bite. However, similar increases in risk were not observed in children of other age groups. There was no reason to believe that children bitten by dogs are at a significantly higher risk of leukemia-lymphoma development than unbitten children.

2134 MICROPROBE ANALYSIS OF LOCALIZED CONCENTRATIONS OF METALS IN VARIOUS HUMAN TISSUES. (E.) Carroll, K. G. (Forsyth Dent. Ctr., Boston, Mass.), J. E. Mulhern, Jr. and V. L. O'Brien. *Oncology* 25(1):11-18, 1971.

Metallic concentrations in human thyroid, lung, breast, stomach, colon, ovary, and rectal benign and malignant tissue were evaluated using electron microprobe analyzer techniques. High metal concentrations of Ca, Ti, Cr, Fe, Ni, Cu and Zn were found in all tissue specimens. The frequency of occurrence of metallic concentrations in malignant tissue, which exhibited many more metal localizations, appeared to be greater than in normal tissue. However, the data are too limited at this time to conclude that there are significant differences in metal content between normal and pathological tissue, or between similar tissues taken from different individuals.

2135 THE AETIOLOGY OF PRIMARY LIVER CANCER IN THE BANTU. (E.) Torres, F. O. (Miguel Bombarda Hosp., Lourenco Marques, Mozambique), I. F. H. Purchase and J. J. Van der Watt. *J Path* 102(3):163-169, 1970.

Liver biopsy specimens taken from a Bantu population in Mozambique at the time of an epidemic of acute hepatitis were from 112 cases of infections hepatitis and 89 cases of "toxic liver damage," and 278 random biopsies including 128 specimens of primary

liver cancer. In view of the high incidence rate of liver cancer among the Bantu (98.2 cases/100,000 population for males) biopsies were compared with material taken from the livers of rats manifesting malignant change and other pathology as a result of maintenance on a diet of sterigmatocystin (10, 20 or 100 mg/kg for 6 months followed by 15, 30 or 150 mg/kg for a further 6 months). Biopsies of human specimens of primary liver cancer showed well-differentiated primary hepatocellular carcinomas with limited bile-duct proliferation and well-developed tumor nodules adjacent to hyperplastic nodules. The pathological picture associated with primary liver cancer was similar to that associated with toxic liver damage and to that observed in livers of rats on the carcinogenic diet. On this basis, it was suggested that liver damage in the Bantu was related to a food-borne toxin, possibly a mycotoxin.

- 2136 INDUCTION OF MURINE LEUKEMIA WITH HUMAN NEOPLASTIC TISSUE. (E.) Dosne Pasqualini, C. (Nat'l. Acad. Med., Buenos Aires, Argentina), F. Saal, A. Pavlovsky and S. L. Rabasa. *Bibl Haemat* 36:304-311, 1970.

One-month-old BALB/c mice were inoculated in the spleen by trocar with cells from hypertrophied human lymph nodes of patients with neoplastic diseases including hemocytoblastoma, fibrosarcoma, Hodgkin's disease, chronic lymphoid leukemia, lymphosarcoma and granuloma. Half of 139 inoculated mice developed leukemias with latencies of 10-46 days; lymphosarcomas and reticulosarcomas as well as true leukemias developed. Leukemias developed in 100% of mice given inocula of hemocytoblastoma, in 88% of mice given fibrosarcoma inocula, and 80% of mice given Hodgkin's disease inocula. Inocula consisting of cultured Burkitt's lymphoma cells EBI and P3J produced leukemias in 30% and 83% of mice, resp. Long term leukemias were observed after 18-20 months in 35% of mice inoculated with human lymphoma cells, including cells from patients with Hodgkin's disease, acute leukemia and hemocytoblastoma. Long-latency leukemias occurred with especially high incidences in mice treated with cells which had produced short-latency leukemias in other mice. Apparently, a mechanism of leukemogenesis is present in BALB/c mice which is activated by inocula of human lymphoma cells.

- 2137 CANCER OF THE CERVIX IN THE PRESENCE OF MULTIPLE TUMORS. (Ger.) Tatra, G. (2nd U. Women's Clin., Vienna, Austria) and A. Kratochwil. *Wien Med Wsch* 121(11):202-204, 1971.

Examination of case records of 324 patients with fatal carcinoma of the cervix revealed an incidence of 4.6% (15) with primary multiple tumors. Histological examination demonstrated the presence of multiple cancer formation in various tissues other than the cervix, including bronchus, bone, kidney, corpus uteri, ovary, gallbladder, stomach, rectum and colon. It is noteworthy that mammary carcinoma

as a secondary cancer was never observed in this clinic. Surprisingly, the second cancer was clinically recognized in only 2 cases, and these only when it was too late to consider treatment. In general, secondary and tertiary cancer sites were identified only at autopsy. Therapy with multiple carcinoma was considered largely unsuccessful.

- 2138 DE-NOVO BRAIN TUMOURS IN RENAL-TRANSPLANT RECIPIENTS. (E.) Schneck, S. A. (U. Colorado Med. Ctr., Denver) and I. Penn. *Lancet* 1(7707):983-986, 1971.

Among 5000 kidney transplant recipients and 170 heart transplant recipients on record, there were 24 instances of the development of mesenchymal tumors in homograft recipients; of these 24 mesenchymal tumors, 11 involved the brain. In 8 of the 11 instances of brain tumors arising following organ transplantation the brain was the only organ involved; in 3 cases tumors were found in the cervical lymph nodes, lung and/or skin in addition to the brain. The age of organ recipients developing brain tumors ranged from 14-46 yr; 7 of the patients were male. In 6 cases, the transplant donor was a blood relative of the recipient. All patients developing brain tumors were treated with prednisone and azathioprine, and 3 of the patients were given anti-lymphocyte globulin. The tumors included 9 reticulum cell sarcomas, 2 unclassified lymphomas, and 1 Kaposi's sarcoma. Tumors developed from 5.5-46 months after transplantation. Brain tumors appeared sooner after transplantation than did non-cerebral mesenchymal or epithelial tumors.

- 2139 COMPARATIVE MORPHOLOGIC STUDY OF BRONCHOALVEOLAR CANCER AND PULMONARY ADENOMATOUS CHANGES IN MAN. (E.) Uzunov, P. (Visshia Med. Inst. Sofia, Bulgaria). *Nauch Tr Vissh Med Inst Sofia* 49(3):83-93, 1970.

Tissues from the lungs of 18 patients with bronchoalveolar carcinoma and from 36 cases of pulmonary adenomatous changes (mainly children) were examined microscopically. Lumina of varying sizes which were similar to alveoli were seen in preparations of both bronchoalveolar cancer and pulmonary adenomatous changes. In both conditions, the lumina were covered with epithelial cells which contained neutral and acid mucopolysaccharides. In bronchoalveolar cancer the epithelial cells showed papillary outgrowths directed towards the lumina, while in adenomatous changes, papillary outgrowths were rare. Cellular atypism and metastases were observed in bronchoalveolar cancer tissues, but not in tissues from patients with adenomatous change. While mucopolysaccharides were found in the lumina of bronchoalveolar cancer tissues, mucopolysaccharides were only rarely found in the lumina in tissues from patients with adenomatous change. Collagens and reticular fibers in bronchoalveolar cancer cells were coarse, while in tissues undergoing adenomatous change they were slender. Apparently, pulmonary adenomatous changes represent a non-neoplastic proliferative regenerative process.

SUBJECT INDEX

- ACETOXY-2-ACETYLAMINOFLUORENE
 - DNA, BINDING (1772)
 - DNA, POLYNUCLEOTIDES (1774)
- ADRENAL GLAND
 - ESTROGEN-DEPENDENT CARCINOMA, RNA AND DNA METABOLISM (1770)
- AFLATOXIN
 - B1, REYE'S SYNDROME, TOXIC REACTION IN MONKEYS (1777)
 - BEAGLE, LIVER CHANGES (1778)
 - DNA, RNA, REVIEW (1744)
 - HEPATIC CHANGES, ENDOPLASMIC RETICULUM, MITOCHONDRIAL ATPASE, RATS (1780)
 - SWAZILAND, LIVER CARCINOMA (1781)
- AGE
 - CARCINOMA, HORMONES, ANTIGENICITY (1740)
 - NEW ZEALAND MICE, MURINE SARCOMA VIRUS, TUMOR REGRESSION (1932)
 - TUMOR, EPIDEMIOLOGY, REVIEW (1725)
- AIR POLLUTION
 - LUNG CANCER MORTALITY, AUSTRALIAN IMMIGRANTS (2049)
- ALKYLATING AGENT
 - CHLORAMBUCIL, BUSULPHAN, BONE MARROW CELL PROLIFERATION (2070)
- AMINOAZOBENZENE
 - N,N-DIMETHYL-4-AMINOAZOBENZENE, LIVER CELL NUCLEI RNA POLYMERASE, OTHER DERIVATIVES, RAT (1783)
- ANTIBODY
 - ANTISARCOMA, HUMAN SARCOMA, VIRUS (1880)
 - 4-AZOGUINOLINE-1-OXIDE, 4-NITROQUINOLINE-1-OXIDE (1994)
 - EPSTEIN-BARR VIRUS, BURKITT'S LYMPHOMA (1973)
 - EPSTEIN-BARR VIRUS, BURKITT'S LYMPHOMA, TAIWAN MONKEY (1972)
 - HETEROLOGOUS ANTIGLIOMA "CARRIER", GLIOMAS, HUMAN (2018)
 - MAMMARY GLAND TUMOR, 7,12-DIMETHYLBENZ(A)ANTHRACENE (1990)
 - TITERS, EPSTEIN-BARR VIRUS, MACAQUE MONKEYS (1974)
- ANTIGEN
 - ADENOVIRUS TYPE 12, HELA CELL (1981)
 - CARCINOMA, HORMONES (1740)
 - CELL-SURFACE, SARCOMAS, HUMAN (2016)
 - CHICKEN FEATHER FOLLICLES, MAREK'S DISEASE HERPESVIRUS (1965)
 - CHORIOCARCINOMA, PLACENTA, KIDNEY (2014)
 - COMPLEMENT FIXATION, HEMAGGLUTINATION REACTION, MURINE LEUKEMIA VIRUSES (1909)

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain two-hundred abstracts and twenty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume IX covers the scientific literature published from July 1970 through June 1971. A cumulative subject and author index for Volume IX will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows:

REVIEW

6 THE ALKYLATION OF TRANSFER RNA BY ENZYMES FROM EMBRYONIC, NEOPLASTIC, AND ETHIONINE-INDUCED LIVER TISSUES. (E.) Hancock, R. L. (Fac. of Medicine, U. Calgary, Alberta, Canada). *Cancer Res* 31(5):620, 1971.

Recent experimental findings concerning aspects of the alkylation of tRNA were reviewed. High molar concentrations of mono- and divalent cations (e.g., 0.2-0.5 M of ammonium ion and 0.01 M of magnesium ion) have been found to enhance tRNA methylase activity; it has been suggested that this enhancing effect on tRNA is due to alterations in the conformation of tRNA. Investigations of 2'-O-methylase activity in liver and hepatoma extracts have shown that tumor tissue extracts methylate tRNA in 2'-O positions. In studies to determine the required substrate characteristics of tRNA methylases it has been found that tRNA methylases do not methylate homopolymers (including polyuridylic, uridylic, guanylic and cytidylic homopolymers). tRNA methylases, however, were able to methylate short fragments of *E. coli* tRNA. Continuing studies have suggested that adult and embryonic cells contain different forms of leucyl-tRNAs and that hepatoma enzymes, when compared with normal liver enzymes, preferentially methylate some *E. coli* tRNAs. Mice fed diets containing 1% ethionine showed an 80% increase in liver tRNA methylase activity compared to mice given a conventional diet. It has been hypothesized that all carcinogenic phenomena may be the result of alterations of minor nucleotides in tRNA; such alterations could affect the genetic information encoded on the DNA of new cells. (41 references)

7 SUMMARY OF SYMPOSIUM ON TRANSFER RNA AND TRANSFER RNA MODIFICATION IN DIFFERENTIATING AND NEOPLASIA. (E.) Zamecnik, P. C. (Massachusetts Gen. Hosp., Boston). *Cancer Res* 31(5):716-720, 1971.

Review of the literature on biochemical characterization of tRNAs, alterations of tRNA during differentiation, and alterations in tRNA and tRNA methylation in neoplasia is presented. I. Base modifications of tRNA such as methylation are believed to change tertiary structure of the tRNAs and to modulate several functions. Data from several experiments indicate the anticodon in amino acid recognition as well as in the established interaction with the codon of mRNA. Evidence points to the dihydrouracil loop as being essential for aminoacyl synthetase recognition. Undermethylated tRNA cannot be aminoacylated as well as normally methylated tRNA. Overmethylated tRNA, and its circular dichroic and optical rotary dispersion pattern and melting profile differ from fully methylated tRNA. II. Evidence indicates that there are more isoacceptor tRNA species in embryonic forms of a tissue than in adult tissue. It is believed that differentiation and loss of synthetic capacities characteristic of cell growth are associated with loss of specific isoacceptor tRNA species, with consequent codon restriction. III. Methylase activity and methylation patterns appear to be more nearly alike between neoplastic and fetal tissue than between fetal and adult tissues. Studies relating chemical methylation to carcinogenesis con-

cluded that while there is no clear indication of which bases of nucleic acids are critical for carcinogenesis, tRNA may be a crucial target. No conclusion was reached on whether all carcinogenesis might be due to alterations of minor bases of tRNA. With the recognition of the Temin-Baltimore enzyme, the idea of some normal feedback from tRNA to the genetic material may not be as remote as first thought. (87 references)

2148 STUDIES ON GENETICALLY ALTERED RNA SPECIES IN *Escherichia coli*. (E.) Carbon, J. (Dept. Biol. Sci., U. California, Santa Barbara) and C. Squires. *Cancer Res* 31(5):663-666, 1971.

Recent investigations of *E. coli* tRNAs altered by mutation were reviewed; experimental work has concentrated on bacterial strains bearing suppressor mutations which revert various missense mutations in the gene specifying the tryptophan synthetase A protein. The A protein mutations, A36, A58 and A78 involve the replacement of specific glycine residues by other amino acids, resulting in an inactive enzyme. The mutations induced codon changes in the A protein message. Specifically, 4 suppressor mutations were listed which resulted in the presence of tRNAs capable of accepting glycine and of inserting it into peptide linkage in response to the altered codon. As an example, the mutation designated *glyT-su36* resulted in a tRNA^{Gly} which could recognize the arginine codon. Some mutations were found to result in the disappearance of a portion of the tRNA; this disappearance produced pleiotrophic effects and was associated with incapability of mutant *E. coli* strains to divide normally on complex media. 2149 ON THE INTERACTION OF CARCINOGENS WITH DNA. (E.) Brookes, P. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., London, England). *Biochem Pharmacol* 20(5):999-1003, 1971.

Carcinogen-DNA interaction is reviewed with respect to N-hydroxylation and esterification which are the probable activation steps preceding the binding of aromatic amine and amide carcinogens to protein; the production of 7-alkylguanine moieties in response to alkylating agents was also discussed. DNA binding, but not RNA or protein binding, correlates with tumor-initiating potency in the case of lactones. Carcinogenic hydrocarbons are metabolized to chemically reactive derivatives which bind to DNA, RNA and protein. The macromolecule which represents the vital target for tumor initiation is still in doubt, although there is a striking similarity in the nature of the metabolically produced ultimate carcinogen, despite the widely different classes of compounds considered. (32 references)

2150 THE POSSIBLE ROLE OF NUCLEIC ACID METHYLASES IN THE INDUCTION OF CANCER. (E.) Magee, P. N. (The Middlesex Hosp. Med. Sch., London, England). *Cancer Res* 31(5):599-604, 1971.

The role of aberrant nucleic acid methylases in the induction of cancer is reviewed. Increased levels

of tRNA methylases have been reported in a variety of tumor tissues and increased levels of methylated purines have been found in the urine of humans with leukemia and in the urine of tumor-bearing animals. In addition, the level of labeling of methylated bases in tRNA increases in animals fed carcinogenic diets. It is agreed among many investigators that the macromolecule must be the crucial cellular target, although compelling evidence for this is lacking. However, all major groups of chemical carcinogens either react directly or give rise to chemically reactive intermediates that react with DNA, RNA, and proteins; on the basis of recent experimentation, DNA has been favored as the most likely cellular target. Yet, lack of evidence for a change in DNA analogous to mutation and the apparent normality of tumor DNA together with the evidence that tumor cells can, in some circumstances, revert to normal cells provides a reason for preferring tRNA as the primary target for chemical carcinogens on the basis of its greater degree of methylation than other types of RNA in cancerous tissue. - 2151 THE EARLY INTERFERENCE OF LIVER CARCINOGENS WITH PROTEIN SYNTHESIS AND ITS POSSIBLE BEARING ON THE PROBLEM OF TUMOR INDUCTION. (E.) Hultin, T. (Wenner-Gren Inst., Stockholm, Sweden). *Biochem Pharmacol* 20(5):1001-1017, 1971.

The effect of liver carcinogens relative to tumor induction is reviewed. Cellular interaction may directly or indirectly affect the synthesis of cell proteins; thus nucleoli are particularly sensitive indicators of the early interference of carcinogens with nuclear functions. Several carcinogens give rise to partial segregation of particulate and fibrillar components of the nucleoli; moderate reduction is seen in the amount of 40-60 min pulse-labeled RNA in response to sublethal doses of CCl_4 , indicating decreased efficiency of nucleocytoplasmic RNA-transportation. Because of its great structural complexity the mitotic part of the cell cycle is particularly sensitive to injury which may lead to errors in the redistribution of genetic material and direct damage to DNA by reactive metabolites may contribute to carcinogenic effects. However, since the important functions of cell nuclei in regulation and differentiation are mediated through cytoplasmic processes also, neoplastic transformation is not necessarily an isolated nuclear phenomenon. (60 references)

- 2152 SUSCEPTIBILITY OF THE GUINEA PIG TO CHEMICAL CARCINOGENESIS. (E.) Argus, M. F. (USPHS Hosp., New Orleans, La.). *Cancer Res* 31(6):917-918, 1971.

Recent discoveries relative to the susceptibility of the guinea pig to chemical carcinogens were reviewed. It has been shown that guinea pigs are highly susceptible to the hepatocarcinogenic action of diethylnitrosamine, dimethylnitrosamine, di-n-butyl nitrosamine, methyl nitrosourea, cycad meal, methylazoxymethanol, aflatoxin and dioxan. Guinea pigs are resistant to carcinogenesis by aromatic amines and amino azo dyes, perhaps due to their limited ability to metabolize these compounds to their N-hydroxy derivatives. It has been shown that guinea pigs treated with N-

hydroxy-2-acetylaminofluorene developed adenocarcinomas in the small intestine, while 2-acetylaminofluorene was inactive. (31 references)

- 2153 RELATIONSHIPS BETWEEN ELECTRONIC TRANSFER ENERGIES, CARCINOGENIC ACTIVITY AND HYDROPHOBIC BINDING TO PROTEIN OF POLYCYCLIC AROMATIC HYDROCARBONS. (Ger.) Franke, R. (Chem. Sec., T. U. Dresden, Germany) and M. Büchner. *Arch Geschwulstforsch* 37(1):45-52, 1971.

Highly significant linear correlations between electron transfer energies ΔE_1 and ΔE_2 and the carcinogenic activity of polycyclic aromatic hydrocarbons were found using experimental data available from the literature. However, these statistical correlations did not allow the prediction of carcinogenic activity for single hydrocarbons. The shortcoming was assumed to be due to other factors such as hydrophobic binding between hydrocarbon and protein which interfered in the mechanism of carcinogenic activity. An analysis of previously obtained aromatic hydrocarbon-protein binding data (with human serum albumin) and carcinogenic activity revealed a relationship that did not affect the correlations between carcinogenic activity and electron transfer energies. Thus the hydrophobic hydrocarbon-protein complex formation could not be considered as a possible secondary interference factor. Therefore the chemical reactivity of the single hydrocarbons rather than the electron transfer energies should be considered the primary factor in their carcinogenicity. (46 references)

- 2154 METAL CARCINOGENESIS IN EXPERIMENTAL ANIMALS. (E.) Sunderman, F. W., Jr. (U. Conn. Sch. Med., Hartford). *Fd Cosmet Toxicol* 9(1):105-120, 1971.

Recent literature dealing with the carcinogenic effects in animals of nickel, beryllium, cadmium, chromium, cobalt, iron, lead, selenium, zinc and titanium compounds was reviewed. Compounds containing beryllium have been shown to cause osteosarcoma in rabbits when administered i.v. Cadmium compounds cause sarcomas and interstitial cell tumors of the testis in chickens, rats and mice when injected or s.c. Special emphasis was given to the literature of nickel carcinogenesis; compounds containing the element have been shown to cause sarcomas, squamous cell carcinomas and anaplastic carcinomas in rats, rabbits, and guinea pigs, when administered by inhalation, i.m., or by an intrapulmonary route. Little evidence was found in the literature to support the hypothesis that metallic compounds present in food cause cancer in man. (170 references)

- 2155 REVERSION IN CELLS TRANSFORMED BY TUMOR VIRUSES. (E.) Macpherson, I. A. (Imperial Cancer Res. Fund Lab., London, England). *Proc Soc Lond* 177(1046):41-48, 1971.

The transformation of animal cells by DNA and tumor viruses was discussed, with special reference to the phenomenon of "reversion" of cell transformation, in which transformed cells lose their virus-transformed characteristics. In some cases of

version, the transformed cells seem to lose the viral genes entirely; loss may occur spontaneously, as in the loss of the Rous sarcoma virus genome by transformed baby hamster kidney cells, or loss may be induced by chromosome loss in the transformed cells, as in the reversion of polyoma virus infection in transformed baby hamster kidney cells. In other instances of reversion, the viral genes remain in the transformed cells, but in an inactivated state, as in the conditional lethal mutants of polyoma virus and avian sarcoma virus. Reversion can be induced by culturing transformed cells on formaldehyde; polyoma virus-transformed hamster cells lose some of their transformed properties in these circumstances. Reversion may also be accomplished by killing transformed cells with fluorodeoxyuridine or bromodeoxyuridine and light. Transformed cells treated with these agents have been shown to lose some of the characteristics of virus-transformed cells, at least temporarily. (25 references)

66 THE VIRAL GENOME IN TRANSFORMED CELLS. (E.) Berg, P. (Stanford U. Sch. Med., Calif.). *Proc Roy Soc Lond* 177(1046):65-76, 1971.

Evidence establishing the presence of viral genes in virally-transformed cells is reviewed. The hypothesis that transformed cells contain the viral genome, initially suggested by the discovery of clear and transplantation antigens in cells infected with DNA tumor viruses, has been confirmed by A-DNA hybridization experiments showing that polyoma virus-transformed cells contain an RNA fraction which is homologous to polyoma virus DNA. Viral DNA has also been demonstrated in virally-transformed cells, and the evidence is that transformed cells contain the whole viral genome. Viral DNA has been shown to be confined to the nuclei of transformed cells. Recent experiments with 3T3 mouse cells transformed with a thermosensitive strain of polyoma virus have suggested that the induction of viral multiplication in transformed cells involves the synchronous occurrence of a unique event, after which DNA synthesis can continue even under non-permissive conditions. In the experiments with polyoma virus, it was also shown that superhelical closed circular dimers and trimers of viral DNA were synthesized as were monomeric molecules; the oligomers amounted to up to 40% of viral DNA. One possible explanation for the formation of large quantities of polyoma oligomers following activation of the thermosensitive strain of polyoma virus in 3T3 cells is that the polyoma genome is integrated into the host-cell chromosomal DNA, where several viral DNA replicons are ordered in tandem at various chromosomal sites. (17 references)

67 SV40 SPECIFIC 'REPRESSOR' IN INFECTED AND TRANSFORMED CELLS. (E.) Cassingena, R. (Cancer Res. Inst., Villejuif, France) and P. Burnier. *Proc Roy Soc Lond* 177(1046):77-85, 1971.

Recent experiments were reviewed which demonstrated that non-permissive SV40-transformed cells contain

a protein which inhibits viral plaque formation in permissive cells. Extracts of SV40-transformed hamster, mouse, or cat cells inhibited plaque formation by SV40-infected monkey cells when the extract was added to the monkey cells with a basic polymer such as poly-L-lysine. Plaque formation inhibition was not seen in cells treated with extracts of normal or spontaneously transformed cells, cells transformed by 3-methylcholanthrene, adenovirus, or polyoma virus. In cells treated with extracts from non-permissive cells, inhibition of plaque formation attained 30-50%. It was found that the plaque formation-inhibiting protein (designated an SV40-specific "repressor") was present in abortive as well as in productive virus infections; however, in productive infections, the repressor was present in reduced amounts only. When extracts of repressor-containing SV40 cells were mixed with extracts of uninfected permissive cells, no inhibition of plaque formation was seen. (11 references)

2158 IMMUNOLOGICAL STUDIES ON A HUMAN TUMOR. DILEMMAS OF THE EXPERIMENTALIST. (E.)

Klein, G. (Inst. Tumor Biol., Karolinska Inst., Stockholm, Sweden). *Israel J Med Sci* 7(1):111-131, 1971.

A review of immunological studies on Burkitt's lymphoma is presented. Fresh Burkitt's lymphoma biopsy cells were exposed to the sera of Burkitt's lymphoma patients and various other donors in an attempt to isolate attached immunoglobulins by the indirect membrane fluorescence technique. The sera reacted more frequently than control sera from donors with other neoplastic or non-neoplastic diseases; most regularly positive sera were derived from patients whose tumors had gone to total regression after chemotherapy. Lymphoma cells, but not bone marrow cells, from the same allogeneic Burkitt's lymphoma donor, reacted regularly, increasing the probability that reactivity was not due simply to the presence of isoantibodies. A variable degree of immunoglobulin coating on the surface of the biopsy cells was of 2 basically different kinds, IgM or IgG or both, and these showed not only a difference in class specificity but also a difference in behavior in relation to the course of the disease; the IgG coat was rarely present in untreated biopsy cells and tended to appear only if the tumor persisted in spite of treatment. Four Burkitt's lymphoma-derived cell lines gave positive membrane immunofluorescence reactions in the indirect test after exposure to the reference serum derived from a patient in long-term regression; 8 controls from normal or leukemic patients were negative. Positively reacting cells revealed the presence of EBV-antigens in more than 1% of the cells compared to less than 1% in the negatively-reacting cells. Whether Epstein-Barr virus-associated membrane antigens are essential for the neoplastic behavior of Burkitt's lymphoma is not clear. (129 references)

2159 IMMUNOLOGICAL FACTORS IN NONSPECIFIC STIMULATION OF HOST RESISTANCE TO SYNGENEIC TUMORS: A REVIEW. (E.) Yashphe, D. J. (Dept.

Immun., Hebrew U. Hadassah Med. Sch., Jerusalem, Israel). *Israel J Med Sci* 7(1):90-107, 1971.

The nonspecific immunogenic potential of endotoxins, mycobacterial moieties and other microbial substances based on clinical observations is discussed. *Corynebacterium parvum* has recently been found to have tumor resistance-inducing properties in experimental animals and *Bordetella pertussis* gives evidence of prolonging remissions of acute leukemia in man. An active methanol extraction residue of BCG has been shown to inhibit malignant tumors, and DNA digests have decreased the incidence or delayed the appearance of spontaneous tumors in mice. Stimulation of immunogenicity before tumor challenge appeared to provide greatest resistance; although there is no direct evidence that these materials stimulate a specific immune response to tumors, it is assumed that elevated host resistance is brought about by an elevated immune response based on observations that tumors are immunogenic and immunization of isogenic hosts protects against subsequent challenge with a graft of the same or of a cross-reacting tumor. That suppression of immune response may be a necessary condition for tumor induction is indicated by the immunosuppressive action of a number of potent carcinogenic hydrocarbons as well as such moieties as antithymocyte serum and anti-lymphocyte serum which can cause increased incidence of tumor formation or leukemia in mice. In addition, specific immunological tolerance to tumor antigens has been suggested as one important factor in the low level of host responsiveness to autochthonous tumors. Immunity to tumors appears to reside largely in populations of lymphoid cells and substances which stimulate tumor resistance also affect either antibody formation or cellular immunity. There may be a variety of cellular functions which can be triggered by non-specific stimulators in place of antigen. (128 references)

- 2160 IMMUNOLOGICAL ASPECTS OF THE RELATIONSHIP BETWEEN HOST AND ONCOGENIC VIRUS IN THE MOUSE MAMMARY TUMOR SYSTEM. (E.) Blair, P. B. (Dept. Bacteriol., U. California, Berkeley). *Israel J Med Sci* 7(1):161-186, 1971.

The immunological response to mammary tumor virus in the mouse is reviewed. Although the neonatally infected mouse is at least partially tolerant to the antigens of the virion and of the infected cells, both noninfected and infected animals are capable of responding immunologically to mammary tumor virus-associated antigenicity. There is some evidence that an infected female mouse which is genetically resistant to the virus may transmit resistance factors to her offspring, but genetically susceptible mice apparently do not produce such resistance factors. Protection against the development of challenge isografts can occur with adoptive transfer of lymphoid cells and transfer of serum antibody from immunized infected mice. Many attempts to immunize infected mice against mammary tumors have resulted, however, in acceleration of tumor growth rather than repression; since the dominant component in immunological protection against solid tissues containing foreign antigens is cell-

associated and not humoral, the approach to immunotherapy should be concerned with evoking cell-associated immunological responses by immunization with membrane bound antigens. An appropriate immunization with inactivated and similar but not identical virus might induce an immunologic response in the host which would be effective against its own virus-induced plasm. (96 references)

- 2161 THE ROLE OF SOME ENDOCRINE GLANDS IN THE PATHOGENESIS OF HORMONE-PRODUCING TUMORS OF THE ADRENAL CORTEX. (Rus.) Sudarev, P. V. (Inst. Exper. Endocrinol. Acad. Med. Sci. U.S.S.R.) and V. I. Kertsman. *Vop Onkol* 17(2):102-107, 1971.

The disruption of the hormonal equilibrium as a factor in the pathogenesis of hormone producing tumors is reviewed. The functional relationship between the hypothalamus, adrenal cortex and gonads is reflected by the morphological alterations occurring in the hypothalamus and adrenal cortex following gonadectomy. Ovariectomy results in an increased gonadotropic stimulation of the adrenal cortex (compensatory action) which leads to the production of adrenal androgens which have different characteristics from the ovarian estrogens. The carcinogenic effect of these hormones is assumed to consist of a long term alteration of the relationship between the proliferative and secretory processes within the tissues subjected to hormonal stimulation. (62 references)

- 2162 MALIGNANT TUMOR OF THE NASOPHARYNX: REVIEW OF LITERATURE, AND OBSERVATION OF 100 CASES (1942-1965). (E.) Hara, H. J. (Loma Linda Univ. Los Angeles, Calif.) *J Otolaryng Soc Aust* 3(2):187-188, 1971.

Nasopharyngeal carcinoma may appear at an early age. 6 of 100 cases observed in the present series occurred in people under 30-yr-old; the condition is more frequent in males than in females, 73 males and 27 females comprising the series. The most common affected age group was the 51-60-yr-old group. The established predilection of the Chinese for nasopharyngeal carcinoma was borne out by the present investigation; 18 cases occurred among Chinese people, making them the second most commonly affected group (after 57 Caucasian cases). Other populations which have been shown to have an unusually high incidence of nasopharyngeal cancer are Kenyan and Malayan Indonesians. While the carcinogenic factors associated with nasopharyngeal carcinoma remain to be elucidated, environmental factors such as irritating dust, fumes, and unsanitary living conditions, are thought to be implicated in the origin of the condition. Of the 100 cases reviewed, 58 were classified as squamous cell carcinoma and 27 as anaplastic carcinoma; most nasopharyngeal tumors are of epidermoid origin. Other less frequently encountered histologic types of tumor were lymphoepithelioma, transitional cell carcinoma, reticular cell sarcoma and lymphosarcoma and adenocystic carcinoma. The prognosis for patients with nasopharyngeal cancer is usually poor, partly for the

on that the condition may remain without overt
ptoms until it has reached an advanced stage.

ROLE OF MYOEPIHELIAL CELLS IN THE DEVELOP-
MENT OF SALIVARY GLAND TUMORS. (E.)
er, G. (Inst. Path., U. Köln, Germany), H. J.
n, O. Kleinsasser and H. G. Schiefer. *Cancer*
) :1255-1261, 1971.

Structural investigations concerning the role
of myoepithelial cells in the growth and structure
of salivary duct carcinomas, salivary gland cylindro-
and pleomorphic adenomas (e.g., "mixed tumors")
of the salivary gland were reviewed. In the duct
carcinoma, myoepithelial cells appear to be intact,
and grow together with epithelial cells. In the
adenoma, myoepithelial cells produce increased
amounts of interstitial material and this, together
with a loosened connection with epithelial cells,
leads to a cribriform pattern and a slower growth
rate than is seen in the duct carcinoma. In the
duct tumor the overproduction of interstitial
material by myoepithelial cells leads to a slow and
atypically benign tumor growth rate. Myoepithelial
cells and elements have also been discerned in those
salivary gland tumors which contain oncocytes:
adenoma lymphomatosum (e.g., "Whartin's" tumor)
and oncocytoma. (16 references)

2178 INTERACTION OF DNA WITH THREE DIMETHYL DERIVATIVES OF BENZ(c)ACRIDINES. (E.)

Chan, E. W. (Cancer Res. Lab., U. Western Ontario, London, Canada) and J. K. Ball. *Biochim Biophys Acta* 238(1):31-45, 1971.

The product which resulted from a mixture of highly polymerized calf thymus DNA solution and a solution of dimethylbenz(c)acridine was analyzed for sedimentation determination, calculation of the binding ratio, and thermal denaturation. The extent of binding for the 7,9-derivative reached a level corresponding to a maximum binding ratio of 1 mole to 16 moles of DNA phosphate; similar results were obtained with the 7,10-derivative, whereas the binding ratio of the 7,11-derivative was about 1 mole to 82 moles of DNA phosphate. With the 7,10-derivative, binding was enhanced 4-fold when the pH was lowered from 8 to 6 and the ratio of un-ionized: ionized 7,10-derivative decreased by a factor of 250; high ionic strength inhibited binding which decreased almost 4-fold when the concentration of NaCl in the standard binding buffer was raised from 10^{-3} to 10^{-2} M. Similarly, the divalent Mg^{2+} and Mn^{2+} cations were more effective in inhibiting binding than were the monovalent cations. The binding of 7,10-dimethylbenz(c)acridine to DNA stabilized the DNA against heat denaturation and lowered the sedimentation rate of the DNA in sucrose gradients. The spectral characteristics of the binding to native and to denatured DNA were qualitatively and quantitatively the same and indicated that the mode of binding of the 7,10-derivative to the 2 forms of DNA was identical.

2179 STUDIES ON THE EFFECTS OF CHEMICALS ON THE PROCESSING OF NUCLEAR RNA: SOME POSSIBLE IMPLICATIONS WITH RESPECT TO CARCINOGENESIS. (E.)

Sporn, M. B. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Biochem Pharmacol* 20(5):1029-1033, 1971.

A hypothesis is advanced for the loss of nuclear RNA associated with the administration of chemical carcinogens to laboratory test animals on the basis of a nuclear enzyme which has been isolated and purified. This enzyme, an exoribonuclease, preferentially attacks single-stranded, non-helical, rapidly-labeled RNA rather than ribosomal or transfer RNA, which results and produces 5'-mononucleotides. Intact Ehrlich ascites tumor cell nuclei treated with actinomycin D, daunomycin, mithramycin and anthramycin (antibiotics which bind to DNA) did not lose the exoribonuclease activity at concentrations of 2 or 20 μ g/ml; at concentrations of 50 μ g/ml only minimal inhibitory effects on the degradation of endogenous rapidly-labeled RNA was seen in isolated nuclei with actinomycin D, daunomycin and mithramycin. A tentative explanation is proposed that a failure of the proper mechanisms for stabilizing newly-synthesized RNA is caused by agents such as actinomycin D or aflatoxin; such a situation may make newly-synthesized RNA more susceptible to exoribonuclease degradation and to alterations which result in carcinogenesis.

2180 HISTOCHEMICAL DEMONSTRATION OF β -GLUCURONIDASE ACTIVITY IN EXPERIMENTAL INFLAMMATORY

PRODUCED BY CROTON OIL IN RATS. (E.) Feher, J. (U. Med. School, Budapest, Hungary), E. H. Jennin, and I. Rannie. *Brit J Exp Path* 52(1):23-26, 1971.

Rats of both sexes were given s.c. and/or i.m. injections of croton oil (0.01 ml) in the right gluteal region; injected rats were killed 1, 2, 3 or 42 days after treatment, and β -glucuronidase activity was assayed in preparations of rat skin using naphthol AS-BI- β -D-glucosiduronic acid as a substrate. Sites of enzyme activity were characterized by the presence of blue granules. In rats given croton oil treatment, epithelial cells and s.c. tissue cells showed at most slight enzyme activity. In rats given croton oil there was a strong granulocytic infiltration of the tissue; the infiltration was most notable on day 3 when croton oil droplets were seen embedded in fibrin cores and in damaged connective tissue cells together with macrophages, monocytes and fibroblasts. During the first 3 days of the inflammatory reaction produced by croton oil, glycosaminoglycans and glycoproteins increased in tissues of treated rats. In treated rats, β -glucuronidase activity increased progressively following croton oil injection and by 6 wk after treatment, enzyme activity was still high. Granules were found intracellularly, especially in the fibroblasts surrounding droplets of croton oil.

2181 ON THE MECHANISM OF ACTION OF CARCINOGENIC AROMATIC AMINES: II. BINDING OF N-HYDROXY-N-ACETYL-4-AMINOBIPHENYL TO RAT LIVER NUCLEIC ACIDS IN VIVO. (E.) Kriek, E. (Netherlands Cancer Institute, Amsterdam). *Chem Biol Interact* 3(1):19-28, 1971.

Male white rats of the highly inbred R-Amsterdam strain were injected i.p. with N-hydroxy-4-acetylamino- 3 H-biphenyl and N-hydroxy-N-2'- 3 H-acetylamino-biphenyl, and carcinogen-liver nucleic acid binding values were observed 24 hr later. Venom phosphodiesterase and alkaline phosphatase digests of liver were analyzed by Sephadex LH-20 column chromatography. Only 11.7% of the total tritium present in the ethanol eluate of liver extracts cochromatographed with N-(guanosin-8-yl)-4-acetylamino-biphenyl. The level of binding of the amines to DNA was about 10% less than in the case of N-hydroxy-2-acetylamino-fluorine. Twenty percent of the total radioactivity bound to ribosomal RNA appeared in the effluent containing unlabeled N-(guanosin-8-yl)-4-aminobiphenyl as a marker. The remaining eluate, constituting 10% of the radioactivity, was eluted in 3 distinct peaks of unidentified material; the major fraction of radioactivity was associated with R_G values of 2.0 and 2.50.

2182 QUANTITATIVE CHANGES IN THE NUMBER OF INFLAMMATORY CELLS IN EXPERIMENTAL INFLAMMATION PRODUCED BY CROTON OIL IN RATS. (E.) Feher, J. (U. Med. School, Budapest, Hungary), E. H. Jennin, and I. Rannie. *Brit J Exp Path* 52(1):27-30, 1971.

rats were injected with croton oil and killed 4 hr or 1-28 days later, at which time the numbers of mast cells in the vicinity of the croton oil-induced inflammation were observed. Mast cells in s.c. tissue and in the gluteal muscle layer area numbered 1008 and 606 (mean numbers in 2.38 mm^2 field) resp., in rats not treated with croton oil. In croton oil-treated rats mast cells in the s.c. tissue and gluteal muscle numbered 1428 and 588, resp., after 4 hr. By 3 days postinjection, s.c. tissue and muscle cell mast cell numbers were 3244 and 1522, resp. Maximum numbers of mast cells were observed on day 11, at which time the numbers of s.c. tissue and muscle cell mast cells were 770 and 2037, resp. After day 11 the number of mast cells began to decline, and on day 28 s.c. tissue had 6363 mast cells and muscle tissue had 881 mast cells. These results suggest the involvement of mast cells in the croton oil inflammation reaction in the rat.

2183 ACTIVATION OF THE CARCINOGEN, N-HYDROXY-2-FLUORENYLBENZENESULFONAMIDE, BY DESULFON-
YLATION TO N-2-FLUORENYLHYDROXYLAMINE *IN VIVO*. (E.)
Malejka-Giganti, D. (Lab. Cancer Res., VA Hosp.,
Minneapolis, Minn.), H. R. Gutmann, R. E. Rydel and
J. Yost. *Cancer Res* 31(6):778-788, 1971.

Male rats (10-12/group) were administered N-hydroxy-2-fluorenylbzenesulfonamide (NHFBS, 4 mg/100 g) and 2-fluorenylbzenesulfonamide (NFBS, 3.8 mg/100 g) and 2-nitrosofluorene (NF, 2.3 mg/100 g) by stomach tube for 4 months; the dosages of each compound were doubled from 4-6 months and then reduced to initial levels for the last month. Another group of male and female rats received 4.5 mg of compounds/100 g i.p. 3 times/wk for 2 wk. A third group of male and female rats were given the compounds by stomach tube or by i.p. administration to test for the presence and identification of urinary metabolites. NFBS appeared to be relatively nontoxic for the rats; weight gains of the rats receiving the compound were 12% less than controls at the end of 2 months. Similar nontoxicity was noted after i.p. injection. NFBS administration resulted in a tumor incidence of 40-63%; carcinogenicity was more marked following i.p. administration. Metabolites such as N-hydroxy-2-fluorenylacetamide (FAA), 3-, 5-, or 7-hydroxy-FAA were isolated from the urine of animals treated with NFBS; the N-hydroxy-2-FAA accounted for 70% of the isolated urinary metabolites. N-Phenyl-2-fluorenylhydroxylamine was found to have weak carcinogenic properties, probably because the molecule cannot be cleaved, as can the N-acylarylhydroxylamines, to form the proximate carcinogen, N-2-fluorenylhydroxylamine.

2184 INDUCTION OF MALIGNANT TUMORS IN RATS BY
ORAL ADMINISTRATION OF 2-IMIDAZOLIDINONE
AND NITRITE. (Ger.) Sander, J. (Hygiene Inst.,
Tübingen, Germany) and G. Bürkle. *Z Krebsforsch*
5(4):301-304, 1971.

Two groups of SIV 50 female rats (6 each) were maintained on a standard diet to which 0.1% 2-

imidazolidinone was added; in addition, group II received 0.12% of sodium nitrite in their drinking water. Food and water were given *ad lib* and the treatment lasted for 150 days. Five of the 6 rats receiving nitrite developed kidney tumors with histological features corresponding to human nephroblastoma. One animal developed lung metastases and another rat developed in addition a papillomatous mammary gland adenoma; the rat with no kidney tumor developed a keratinizing squamous cell carcinoma in the parotid region. No tumors were observed in the group that did not get nitrite; all rats in this group survived to the end of the experimental period (when the last rat of group II died) and were then sacrificed 311 days after the beginning of the experiment. The induction of malignant tumors by oral administration of 2-imidazolidinone and nitrite indicated that the amide group is easily converted into the corresponding carcinogenic nitrosoderivative *in vivo*.

2185 ANIMAL EXPERIMENTS ON THE CARCINOGENIC ACTION OF METHOTREXATE AND CYCLOPHOSPHAMIDE.
(Ger.) Roschlau, G. (Med. Acad. Carl Gustav Carus, Dresden, Germany) and J. Justus. *Deutch Gesundh* 26(5):219-222, 1971.

Biweekly injections (i.p., 25 mg/kg x 30, total dose of 750 mg) of cyclophosphamide and 55 mg (0.1 mg/kg/day, p.o. drinking water) of methotrexate were administered to male and female XVII/B1n and AWD mice. Both agents at these therapeutic dose levels showed definite carcinogenic effects in 18-24 months in all groups, with lung adenoma and carcinoma predominantly present and, to a lesser degree, hepatoma and skin carcinoma and sarcoma. The rate of lung tumor induction was markedly above that of spontaneous tumor formation, with methotrexate treatment showing particularly high incidence. Pregnancy often disposed towards a higher incidence of malignancy in cyclophosphamide-treated animals (an observation of significance in human oncology) and untreated offspring of mothers treated with cyclophosphamide during pregnancy showed increased rate of tumor formation, suggesting transplacental oncogenetic drug action.

2186 PANCREATIC ISLET CELL TUMORS PRODUCED BY
THE COMBINED ACTION OF STREPTOZOTOCIN AND
NICOTINAMIDE. (E.) Rakieten, N. (South Shore
Analytical and Res. Lab., Inc., Islip, N.Y.), B. S.
Gordon, A. Beaty, D. A. Cooney, R. D. Davis and
P. S. Schein. *Proc Soc Exp Biol Med* 137(1):280-283, 1971.

Male rats were given streptozotocin and/or nicotinamide according to 1 of 3 protocols: a single i.v. injection of 50 mg/kg streptozotocin together with 2 i.p. injections of 350 mg/kg nicotinamide; 50 mg/kg streptozotocin alone; or 350 mg/kg nicotinamide alone. Controls were given an 0.025 M solution of citric acid in saline. Pancreatic islet cell tumors developed in 64% of the rats given both streptozotocin and nicotinamide; tumors first ap-

peared 226 days after treatment, and 83% of tumors had developed by days 438-547. Only 1 islet cell tumor developed in rats given streptozotocin alone, and no islet cell tumors developed in either nicotinamide-treated rats or in controls. Tumors appeared to be reddish brown bodies weighing 50-70 mg and were insulin-secreting; they were first seen in the tail of the pancreas adjacent to the hilus of the spleen. The tumor cells had centrally placed nuclei which lacked nucleoli.

- 2187 CARCINOGENIC ACTION OF DIMETHYLSULFOXIDE (DMSO). (Ger.) Lohs, Kh. (Inst. Chem. Toxicol. D.A.W., Berlin-Buch, Germany), W. Damerau and T. Schramm. *Arch Geschwulstforsch* 37(1):1-3, 1971.

Young Wistar rats (8 wk), injected s.c. 10 times biweekly with either or both $TiCl_3$ + DMSO + H_2O and H_2O_2 + DMSO + H_2O showed no signs of tumor formation over the subsequent year. This is contrary to the view that methyl and methane sulfonyl radicals found in the reaction of DMSO and H_2O_2 in the presence of heavy metal ions may have carcinogenic effects.

- 2188 IMMUNOSUPPRESSIVE ACTIVITY OF THE ONCOGENIC PURINE DERIVATIVE 3-HYDROXYXANTHINE. (E.) Teller, M. N. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.) and I. Smullyan. *Israel J Med Sci* 7(1):66-71, 1971.

Young male rats were injected with 1 of 4 carcinogens and the degree of immunosuppression induced by the agents was observed; the carcinogens included 3-hydroxyxanthine (1 or 7 mg), 3-methylcholanthrene (1 or 6 mg), cortisone (20 mg) and cyclophosphamide (2.6 mg). To test the effects of carcinogens on the hemagglutinin antibody response, rats were given injections of antigenic sheep red blood cells following carcinogen administration. Saline-treated rats showed (\log_2) antibody titers of 12.0 to sheep red blood cells compared to 3-hydroxyxanthine-treated rats which showed titers of 5-9. Methylcholanthrene and cortisone inhibited the antibody response to a similar degree as 3-hydroxyxanthine; cyclophosphamide almost entirely suppressed the antibody response (titers of 0.6). The effect of carcinogens on homograft response was studied in rats implanted with sarcoma tissue. In untreated rats and in rats treated with saline, tumors developed in 30 and 0% of cases, resp. In rats given 7 mg of 3-hydroxyxanthine, tumors developed in 50% of cases, and in rats given 1 mg of this agent the tumor incidence was 20%. In rats given methylcholanthrene in addition to 3-hydroxyxanthine the tumor incidence was 40%, and in rats given 8 mg of cortisone in addition to carcinogen the tumor incidence was 100%. Cortisone enhanced the effect of 3-hydroxyxanthine.

- 2189 MORPHOLOGICAL ALTERATIONS OF THE ANIMAL SKIN FOLLOWING SINGLE APPLICATION OF CARCINOGENIC HYDROCARBONS. (Rus.) Vasil'yeva,

N. H. (Inst. Exp. Clin. Oncol. Acad. Med. Sci. U.S.S.R., Moscow). *Biull Eksp Biol Med* 71(3):116-119, 1971.

The morphology of the skin reaction to a single application of 7,12-dimethylbenz(a)anthracene (DMBA), 3-methylcholanthrene (MC) benzo(a)pyrene (BP), pyrene (P) or anthracene (A) was investigated in 287/A and C57BL randombred mice and in Wistar and guinea pigs. Benzene solutions of the test hydrocarbons (1% BP or P, 0.5% MC or A or 0.25-0.5% DMBA soln) were applied topically on the intercostal region; the mice were given 2 drops and the rats and guinea pigs were given 5 drops of a test compound soln. The most explicit hyperplastic alterations of the epidermis, in order of intensity, were induced by DMBA, MC and BP and correlated with the carcinogenicity of these compounds. The most intense reactions occurred in mouse skin; a severe decrease in sebaceous glands 3-5 days after carcinogen treatment along with hyperplastic alterations of the epidermis were observed; the sebaceous glands were intact during the whole experimental treatment when exposed to P or A. BP-induced dystrophic changes in the sebaceous gland cells occurred on the 1st day after its application. DMBA induced the first signs of atypia and epithelial polymorphism in 9 days and focal proliferation in 11 days following application. Regeneration of the sebaceous glands after MC or BP treatment was observed 7-9 days after 15-17 days, resp., after DMBA application. The premalignant transformations of the epidermis were usually correlated with specific alterations of connective tissue. Fluorescence studies of fresh frozen mouse skin sections revealed the longest retention time within the sebaceous glands for BP (up to 7 days); BP retention time was 3 days for MC and 1 day for DMBA.

- 2190 PYRROLE PIGMENTS OF ORGANS IN 2-AMINO-FLUORENE-INDUCED CARCINOGENESIS IN RATS. (Ger.) Zawirska, B. (Inst. Pathol. Anat. Acad. Med. Sci., Wroclaw, Poland), K. Medras and Sosnik. *Zbl Allg Path* 114(1):41-50, 1971.

The chronic feeding of 2-acetylaminofluorene (2-AAF) (2 mg daily for 3-14 months) induced epithelial tumors in various organs, but particularly in the liver, of Wistar rats. The transplanted liver carcinomas produced pulmonary metastases. Macrofluoroscopic examination of the tissues and organs and the liver cell carcinomas showed no porphyrin fluorescence except in the Harderian glands, which fluoresced red. Microfluoroscopic examination of livers at different stages of the 2-AAF feeding and of the transplanted liver cell carcinomas were all negative for red fluorescence. Biochemical determinations of uroporphyrin, coproporphyrin and protoporphyrin performed between 75-380 days from the beginning of the experiment showed similar values in experimental and control animals; the highest porphyrin values were found in Harderian glands. The concentration of uroporphyrin/g of tissue was higher of the porphyrins in all organs. During porphyrin extraction from tissues, particularly from liver cell carcinomas, a greenish substance was observed.

ich resembled bile pigments but behaved to a certain extent like porphyrin. It is suggested that this substance is derived from the splitting of the pyrrole ring.

91 INHIBITION OF PITUITARY-INDUCED NODULAR HYPERPLASIA IN MAMMARY GLANDS OF C3H MICE FED A PHENYLALANINE-DEFICIENT DIET. (E.) Forni, A. ("Luigi Devoto" Work Clin., U. Milan, Italy), E. Pacifico and A. Limonta. *Arch Environ Health* 22(3):373-378, 1971.

male virgin mice of strain C3H/Crgl were maintained for 19 wk on diets containing phenylalanine w/w levels ranging from 0.075-0.300%; mammary glands of mice were stimulated by a pituitary iso-raft implanted under the kidney capsule for the first 13 wk of phenylalanine feeding. Phenylalanine deficiency in the diet was found to increase the development of mammary hyperplastic nodules. Mice given 0.075-0.090% phenylalanine developed no nodules; 0-16% of mice given 0.120% phenylalanine developed nodules; 50-100% of mice given 0.150-0.300% phenylalanine developed nodules. High levels of dietary phenylalanine increased the body wt of mice. The ratio of organ wt to body wt for ovaries, but not liver, kidneys or adrenals, was lower for mice fed with 0.075-0.120% phenylalanine. Ovaries of mice in this experimental group lacked corpora lutea.

92 MOLECULAR SPECIFICITY OF THE TUMORIGENIC ACTION OF ETHIONINE: THE INACTIVITY OF S-ETHYL-L-CYSTEINE: ACTION ON RESPIRATORY PARAMETERS. (E.) Argus, M. F. (Dept. Med., Tulane U., New Orleans, La.), L. E. White, G. M. Bryant, J. C. Hoskins and C. Hoch-Ligeti. *Z Krebsforsch* 73(3):201-208, 1971.

The structure-effect relationship of the ethionine molecule was investigated. Oncogenicity of ethionine was compared to that of S-ethyl-L-cysteine (SELC) and their effects on the phosphorylation processes in rat liver mitochondria using α -ketoglutarate, hydroxybutyrate or succinate as substrates were investigated. Male Wistar rats received a total of 6 g of SELC p.o. within 90 wk or a total of 6 g of ethionine p.o. within 52 wk. SELC appeared to be non-oncogenic while ethionine produced a 100% incidence of liver tumors. Ethionine produced a decrease both the P/O ratio and the respiratory control index (RCI) *in vivo* in female but not in male rats. The P/O ratio decreased in female rat mitochondria upon ethionine treatment *in vitro*. SELC had no effect on the P/O ratio when assayed with either of the above-mentioned substrates. No alterations in the QO_2 were observed to be produced by ethionine or SELC. The increased availability of ATP, through "trapping" of adenosyl moieties by ethionine, seemed to be masked by other alterations in ATP biosynthesis. The effects of ethionine on the phosphorylation processes seemed to be related to its fatty liver inducing properties in female rats rather than to its

carcinogenicity. The lack of oncogenic effects elicited by SELC seemed to indicate the necessity of the 4 carbon chain structure in the ethionine molecule.

2193 CHROMOSOME STUDIES IN WORKERS EXPOSED TO BENZENE OR TOLUENE OR BOTH. (E.) Forni, A. ("Luigi Devoto" Work Clin., U. Milan, Italy), E. Pacifico and A. Limonta. *Arch Environ Health* 22(3):373-378, 1971.

Peripheral blood lymphocytes from 34 workers in a rotogravure printing plant were examined for chromosomal aberrations; 10 of the workers had been exposed to benzene and/or toluene in the course of their work, and 24 of the workers had been exposed to toluene only. Duration of exposure to benzene and toluene ranged from less than 1 yr to 22 yr, while duration of exposure to benzene alone (2 cases) was 2-3 yr and duration of exposure to toluene alone ranged from 3-15 yr. Subjects ranged in age from 29-58-yr-old. The incidence of unstable chromosome changes was higher in the group exposed to benzene than in the group exposed to toluene (incidences of 1.66% and 0.80%, resp.); however, the incidence of unstable chromosome changes in the toluene group was not significantly different from that in a group of matched controls not exposed to either benzene or toluene (0.61% incidence in controls). The incidence of calculated breaks in chromosomes undergoing unstable changes was also higher in the benzene group than in the toluene group or in controls; the percentages of calculated breaks in the benzene group, the toluene group and the controls were 1.87, 0.83 and 0.67%, resp.

2194 STIMULATORY EFFECTS OF CHEMICAL CARCINOGENS IN CELL CULTURES. (Rus.) Parkhomenko, I. I. (Inst. Chem. Phys., Acad. Med. Sci., U.S.S.R., Moscow) and I. S. Irlin. *Vop Onkol* 17(3):81-85, 1971.

Small doses of the chemical carcinogens, benzo(a)-pyrene, (0.02, 0.1, 1 mg/ml) and 7,12-dimethylbenz(a)anthracene (DMBA 0.01, and 0.1 mg/ml) had a stimulatory effect on the *in vitro* growth of hamster cells transformed by polyoma virus strain 874, but these same doses produced an inhibitory effect on the cell growth of normal hamster cells and in cultures infected with the 866 and 610 polyoma virus strain; 3-methylcholanthrene (MC) (0.2 and 1 mg/ml) manifested stimulatory effects on the 874 and also on the 866 polyoma virus-infected cells and was the least toxic of the carcinogens; when tested at doses of 0.2, 1 and 5 mg/ml, MC decreased the *in vitro* growth of the 610 strain. In general, low doses of the carcinogens had a stimulatory effect, while doses as high as 5 mg/ml had an inhibitory effect on *in vitro* culture growth. The noncarcinogenic analogs, purine and anthracene, were less toxic and were most effective stimulants of the 874 cell line at a dose of 0.1 mg/ml. The simultaneous addition of 2 carcinogens at the doses of 0.1 for DMBA and 1.0 mg/ml for MC also proved to be growth stimulating. A stimulatory dose of anthra-

cene (1.0 mg/ml) could not alleviate the toxic effects of DMBA at 1.0 mg/ml, when the 2 compounds were used simultaneously.

- 2195 THE HAMSTER AS A MODEL FOR METAL CARCINOGENESIS. (E.) Furst, A. (Inst. Chem. Biol., U. San Francisco, Calif.) and M. C. Schlauder. *Proc West Pharmacol Soc* 14(68):68-71, 1971.

Syrian hamsters of both sexes after 3-4 wk were given i.m. injections of pure metal and organometallic compounds once a month. The compounds tested included nickel powder, nickelocene, and titanocene dichloride. The incidence of tumors developing in treated hamsters was not high and ranged from 0 tumors in 50 hamsters given 5 mg nickelocene to 4 tumors in 29 hamsters given 25 mg nickelocene. Metallic compounds produced a much higher tumor incidence (36-76%) when administered to rats. Tumor-like nodules appeared with 3 months from the start of metal treatments in hamsters and regressed over time; rats did not develop nodules until 7-10 months after the start of the carcinogenic regimen. In hamsters receiving transplants of tumors induced by the metal carcinogens, a 100% tumor-take was seen. Tumors induced in hamsters by the metals were poorly differentiated fibrosarcomas composed of spindle-shaped cells and rich in collagen. The presence in hamster tumors of aggregations of plasma cells and lymphocytes suggested a host immune response to the metal carcinogens which was not observed in the rat.

- 2196 THE ROLE OF OVERHEATED FOOD FATS IN CARCINOGENESIS. (Rus.) Turkiya, N. B. (Sci. Res. Inst. Oncol. Min. Pub. Hlth. Georgian S.S.R., Tiflis, U.S.S.R.), G. L. Chechelashvili, P. N. Krasnyanskaya, D. Sh. Beniashvili and L. N. Dzagnidze. *Vop Pitan* 1:31-34, 1971.

The carcinogenicity of butter and sunflower oil heated to 160-180°C for 30-40 min was tested by p.o. and i.m. treatment of 260 randombred rats. P.O. treatment of 100 rats consisted of 3 ml of heated oil or butter alone on alternate days for 1.5 yr or combined with 3 doses of 2 mg of benzo(a)pyrene (BP) given at 1 wk intervals at the beginning of the experiment. The i.m. treatment (160 rats) consisted of 6 injections of natural or heated butter or oil (2 ml at 10-day intervals) alone or combined with a single dose of 1 mg of BP dissolved in benzene. No tumors occurred in the p.o.-treated rats; 19 of 116 i.m.-treated rats developed tumors 4 months after the beginning of the experiment. The highest incidence of tumors (5 out of 10 rats) was noticed among the animals exposed to heated butter associated with BP and no tumors occurred in the rats treated with unheated fats. The development of tumors could be attributed to the formation of thermoresistant oxidation products during the heating of the tested fats.

- 2197 IN VITRO TRANSFORMATION OF HAMSTER CELLS BY POLYCYCLIC HYDROCARBONS: FACTORS INFLUENCING THE NUMBER OF CELLS TRANSFORMED. (E) DiPaolo, J. A. (Natl. Cancer Inst., Natl. Inst. Bethesda, Md.), P. J. Donovan and R. L. Nelson. *Nature* 230(16):240-242, 1971.

Primary, secondary or tertiary Syrian hamster cells 2-4 days old were exposed to benzo(a)pyrene (2.5 µg/ml) or balanced salt solution and diluted with complete medium one day after the hamster embryo cells had been seeded with irradiated rat cells feeders. Under stereoscopic microscopy primary secondary cultures exhibited a wide variety of different types of colonies, and a proportional decrease in variety was noted with increased concentration of the carcinogen. Twelve different cell morphologies were recognized among fibroblast-like and epithelial-like transformations; organ cells revealed less variety. The seeding of 500 cells provided for transformation/cell percentage ranging from 0.2 to 0.73%; the cloning efficiency of the different cultures in the presence of carcinogen varied from low of 3% to a high of 5.9% which occurred when feeders were added 48 hr before the addition of hamster cells and lowest when the feeders were added subsequent to the hamster cells. Transformation was influenced by the number of feeders used; 2 irradiated rat cells had a relatively poor feeding effect in contrast to 50-100,000 cells which produced optimal effects. However, the addition of a million feeder cells practically suppressed the recognition of transformed colonies.

- 2198 PROPERTIES OF CHROMATIN FROM LIVER AND FROM A CHEMICALLY INDUCED MINIMAL DEVIATION HEPATOMA OF THE RAT. (E.) Smith, C. E. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), P. T. Mora. *Biochim Biophys Acta* 232(4):643-651, 1971.

A minimal deviation hepatoma carried by i.m. transplantation in female Buffalo strain rats revealed its DNA and chromatin UV spectra and the thermal denaturation profiles of its chromatin to be nearly identical to their liver counterparts. Higher content of RNA (RNA/DNA=0.38) was associated with the hepatoma chromatin than in liver chromatin (RNA/DNA=0.15). The nucleotide compositions of *in vitro* transcribed RNA products catalyzed by *E. coli* or *M. luteus* polymerase using DNA templates from hepatoma and liver chromatin were similar to each other. All RNA products had a high A+U/G+C ratio of 1.1-1.3. The kinetics of ¹⁴C-CMP incorporation (which increased for at least 40 min at 37°C) and the divalent ion requirements (4mM Mg²⁺, 1 mM Mn²⁺) of DNA-directed *E. coli* RNA polymerase with hepatoma chromatin template appeared to be similar to those known for liver chromatin.

- 2199 CHEMICAL CARCINOGENS AND RNA. (E.) Weinstein, I. B. (Inst. Cancer Res. Dept. Med., Columbia U., New York, N.Y.), D. Grunberger, S. Fujimura and L. M. Fink. *Cancer Res* 31(5):651-655, 1971.

highly purified preparation of *Escherichia coli* tRNA^{fMet} was modified to a low extent by reaction with 1.25×10^{-3} M ^{14}C -N-acetoxy-2-acetylaminofluorene (NAAAF) for 90 min, and the unreacted and AAF-modified tRNA^{fMet} were separated on a BD-cellulose column. The modified tRNA^{fMet} (AAF-tRNA^{fMet}, 5% yield) displayed considerable absorption at 260 nm and melted at a lower temperature and had a lower total hyperchromicity than the control material. Size T₁ treatment and DEAE-Sephadex A-25 column chromatography of AAF-tRNA^{fMet} resulted in the isolation of mainly AAF-modified guanosine. Treatment with pancreatic RNase and chromatography on BD-cellulose DEAE-Sephadex A-25 yielded an AAF-labeled oligonucleotide which seemed to be a G-G-pyrimidine segment. Use of models and analysis of residues showed that AAF becomes covalently linked to position 8 of guanosine residues. This attachment may distort the formation of the tRNA, thereby altering interactions with aminoacyl-tRNA synthetases, codons, and/or ribosomes, resulting in widespread disturbances of the translation apparatus, with secondary consequences with respect to cell differentiation, regulation and autonomy.

ONCOGENIC RESPONSE OF RAT SKIN, LUNGS, AND BONES TO VINYL CHLORIDE. (E.) Viola, L. (Regina Elena Inst. Cancer Res., Rome, Italy), Bigotti and A. Caputo. *Cancer Res* 31(5):516-522, 1971.

The rats were exposed to vinyl chloride vapors for 5 hr per day, 5 days per wk for 12 months; the vinyl chloride was diffused into the air of the containers which held the rats in amounts of 3% vinyl chloride (30,000 ppm). Almost all the rats developed tumors of the skin and lungs. Among 17 rats surviving the 12 month course, all had skin tumors and 6 had lung tumors; 5 of the 17 had bone tumors. Most of the tumors were epidermoid carcinomas; there were also epidermoid carcinomas and 2 epidermoid carcinomas of the keratinizing type. Among lung tumors, there were 3 adenocarcinomas, a squamous cell carcinoma and an adenocarcinoma. Bone tumors were localized in the metacarpal and metatarsal bones of 4 extremities; all were osteochondromas. Skin tumors were localized in the area of the submaxillary and parotid glands.

QUANTITATIVE CHANGES IN UNSCHEDULED DNA SYNTHESIS IN RAT MUSCLE CELLS AFTER DIFFERENTIATION. (E.) Hahn, G. M. (Stanford U. Sch., California), D. King and S.-J. Yang. *Nature* 231(526):242-244, 1971.

Uninucleated rat muscle cells and fibroblasts obtained from rat embryos on the nineteenth day of gestation were exposed to methyl methane sulfonate (MMS) for 7 hr followed by labeling with ^3H -thymidine for 3 hr. Exposure for 3 hr to 1 mM MMS reduced the number of cells with more than 100 grains, indicating inhibition of normal DNA synthesis. However, the number of unlabeled cells was also greatly reduced and unscheduled DNA synthesis. Nuclei from myo-

tubes revealed almost no label even after exposure to MMS; however if the time of exposure was greatly increased, unscheduled DNA synthesis could be detected.

2202 POLYCYCLIC AROMATIC HYDROCARBONS IN SMOKED FISH, "KATSUBUSHI". (E.) Masuda, Y. (Fac. Med., Kyushu U., Japan) and M. Kuratsune. *Gann* 62(1):27-30, 1971.

Chromatography on alumina columns and on partially acetylated paper and UV absorption spectroscopy were used to determine the content of polycyclic aromatic hydrocarbons in the smoked and dried fish dishes Katsubushi, Sababushi, and Urumbushi. These dishes are prepared by smoking the flesh of bonito, mackerel and sardine over wood fires for periods of about 1 wk. Polycyclic aromatic hydrocarbons detected in the fish included phenanthrene, pyrene, fluoranthrene, benz(a)anthracene and benzo(a)pyrene. Katsubushi generally contained more hydrocarbons than the other dishes. The amounts of benzo(a)pyrene found in Katsubushi, Sababushi and Urumbushi were 37, 12 and 2 $\mu\text{g/kg}$, resp. It was found that these Japanese smoked fish contained significantly higher concentrations of polycyclic aromatic hydrocarbons than smoked fish from other countries.

2203 CYTOGENETIC EFFECTS OF CYCLOHEXYLAMINE AND N-OH-CYCLOHEXYLAMINE ON HUMAN LEUCOCYTES AND CHINESE HAMSTER BONE MARROW. (E.) Brewen, J. G. (Oak Ridge Nat. Lab., Tenn.), F. G. Pearson, K. P. Jones and H. E. Luippold. *Nature* 230(9):15-16, 1971.

Short term human leukocyte cultures were exposed to 20, 100, or 500 $\mu\text{g/ml}$ of cyclohexylamine (CHA) at the G₀, G₁, S, or G₂ phase of the mitotic cycle; leukocytes were also exposed to 25, 50, 100, 200, or 250 $\mu\text{g/ml}$ of N-hydroxycyclohexylamine (N-OHCHA) in all mitotic stages except the G₀ phase. In related *in vivo* experiments, hamsters were given implanted diffusion chambers containing human leukocytes and treated with CHA. The hamsters were killed 60-66 hr after implantation and the diffusion chambers were withdrawn for examination. In none of the experiments was there an increase in the incidence of chromatid breaks occurring in CHA-treated or N-OHCHA-treated leukocytes. Asymmetric chromosome exchanges (including rings and dicentric) were seen to have a very low frequency in treated and in untreated leukocytes.

2204 COCARCINOGENESIS STUDIES ON MOUSE SKIN AND INHIBITION OF TUMOR INDUCTION. (E.) Van Duuren, B. L. (New York U. Med. Ctr., New York), T. Blazej, B. M. Goldschmidt, C. Katz, S. Melchionne and A. Sivak. *J Nat Cancer Inst* 46(5):1039-1044, 1971.

Female strain ICR/Ha Swiss mice were given topical applications of linalyl oleate and linalyl acetate

together with benzo(a)pyrene (1 or 5 μ g 3 times/wk) to test the co-carcinogenic effects of tobacco leaf and smoke derivatives. Other derivatives including phenol, solanesol, rutin, morin and linalyl laurate were also tested. Linalyl oleate and linalyl acetate showed slight co-carcinogenic activity, while phorbol myristate acetate was strongly co-carcinogenic. Linalyl acetate, bornyl acetate, bornyl laurate and bornyl oleate showed no co-carcinogenic activity. Phenol, rutin and morin produced decreased tumor yield by comparison to the yield produced by benzo(a)pyrene alone.

- 2205 THE EFFECT OF AFLATOXIN B₁ ON RNA SYNTHESIS AND BREAKDOWN IN NORMAL AND REGENERATING RAT LIVER. (E.) Wagner, L. (Med. Clin., U. Heidelberg, Germany) and J. Drews. *Europ J Cancer* 6(6):465-476, 1970.

Partially hepatectomized rats were given i.p. injections of 1.0-1.25 mg/kg of body wt aflatoxin B₁, and the ensuing changes in the metabolism of nuclear RNA in the regenerating liver were observed. A 30-50% decline in the incorporation of labeled RNA precursors to liver RNA was seen within 2.5 hr after aflatoxin treatment. Aflatoxin was found to hinder the formation of the 35S ribosomal precursor RNA and of 28S RNA. A change to more DNA-like values was seen in the ³²P-nucleotide composition of total nuclear RNA extracted after pulse-labeling with ³²P-ortho-phosphate. A rise in the AMP + UMP/CMP + GMP ratio of the ³²P-labeled RNA followed aflatoxin treatment; this rise was more marked in regenerating liver than in normal liver from intact rats. *In vitro* experiments demonstrated that nuclei from aflatoxin-treated rats had less capacity to synthesize RNA than did nuclei from untreated rats.

- 2206 THE INFLUENCE OF POSTNECROTIC CIRRHOSIS ON AFLATOXIN CARCINOGENESIS IN RATS. (E.) Sun, S.-C. (United States Naval Med. Res. Unit No. 2, Taipei, Taiwan), R.-D. Wei and B. T. Schaeffer. *Lab Invest* 24(5):368-372, 1971.

Crude aflatoxin preparations containing 57% B₁, 41% G₁ and trace amounts of B₂ and G₂ dissolved in N,N-dimethylformamide-propylene glycol (1 mg/ml) were administered to 4 experimental groups of rats 4-6 wk following CCl₄ and/or ethanol pretreatment. Rats with moderate to severe CCl₄-induced postnecrotic cirrhosis given 200 μ g/wk of toxins (i.p. for 3 wk) developed hepatoma in 11 of 16 cases and advanced liver cell atypia in 5 of 16 cases within 12 wk; rats with ethanol-induced fatty liver developed no tumors under similar experimental conditions. When treated for 8 wk with similar weekly amounts of toxin 13 of 20 rats died within 37 wk (3 with hepatocarcinoma); of the 7 surviving rats 2 developed liver cell cancer, 3 had advanced hepatocellular atypia, and 2 had atypical canalicular hyperplasia. Postnecrotic cirrhosis seemed to promote aflatoxin-induced hepatocarcinogenesis with early malignant transformations occurring within the cirrhotic nodules.

- 2207 AFLATOXIN B₁: THE KIDNEY AS A SITE OF ACTION IN THE MOUSE. (E.) Akao, M. (Dept. of Nutrition and Food Science, Massachusetts Inst. Tech., Cambridge), K. Kuroda and G. N. Wogan. *Lipid Sci* 10(9):495-501, 1971.

Aflatoxin B₁ was injected i.p. to 100-120 day-old CFW Swiss mice at 60 mg/kg, single dose. ¹⁴C-Orotic acid (22.6 C/mole) was injected at a dose of 25 μ mol, 1, 12, 24 or 72 hr after toxin injection. Three days later, the mice were killed and incorporation of precursor into RNA of liver and kidney tissues was determined. A 50% suppression of precursor incorporation was evident in the kidney within 3 hr after toxin administration and persisted through the 72 hr period of study. The RNA content of kidneys decreased rapidly to less than 50% of control values and pronounced hemorrhagic lesions developed in the medullary portions between 48 and 72 hr. No similar alteration in either precursor uptake or histology was seen in the liver. RNA polymerase activity decreased from 258 to 138 p moles UTP/mg DNA under Mg²⁺ activation and from 652 to 454 p moles UTP/mg DNA under Mn²⁺ activation in the kidney of toxin-treated mice. No inhibition of RNA polymerase under either condition of activation was apparent in liver nuclei isolated from aflatoxin-treated mice. The responses occurring in kidneys but not in the liver of mice may be due to the presence in mouse kidney of chromatin with sites of interaction for the toxin which are not present in the liver.

- 2208 INDUCTION OF RECESSIVE LETHALS IN *Drosophila melanogaster* BY AFLATOXIN B₁. (E.) Lamb, M. J. (Zool. Dept., Birkbeck Coll., London, England) and L. J. Lilly. *Mutat Res* 11(4):430-433, 1971.

Male *Drosophila melanogaster* were given p.o. dose of 0.02 mg aflatoxin B₁ in a 0.5% dilution of DMSO administered to females; the incidence of 11nd chromosome recessive lethals was observed in the offspring of the aflatoxin-treated *Drosophila*. The percentage of lethals found in the offspring of 100 *Drosophila* fed DMSO ranged from 0-0.69 \pm 0.34%, while the incidence of lethals among offspring of *Drosophila* given aflatoxin B₁ ranged from 0.53 \pm 0.30 to 3.66 \pm 0.30.

- 2209 ACUTE TOXICITY OF AFLATOXIN G₁ TO THE RAT. (E.) Butler, W. H. (Med. Res. Council, Carshalton, Surrey, England) and W. Lijinsky. *J Path* 102(4):209-212, 1971.

Male rats were treated with aflatoxin G₁ (0.15-0.30 mg/ml) either by i.p. injection or by gavage, and the ensuing lesions were described. Diffuse parenchymal cell necrosis, especially prominent in the periportal zone, was seen in the livers of rats 2-7 days after treatment. After 7 days, the major change seen in liver parenchymal cells was that nuclei became enlarged and hyperchromatic. By 2 days after treatment proliferation in bile duct epithelium was seen; proliferation became maximal at 6-7 days after treatment. In more severely affected

ated rats, hyperplastic nodules and areas of angiofibrosis were present. By 1-2 days after treatment the epithelium of the straight segments of the proximal tubules of the kidney showed eosinophilic cytoplasm; at 3-4 days the kidney tubules showed necrosis. By 3-4 wk after treatment, the only abnormality seen in the kidneys of treated rats was the presence of many large hyperplastic epithelial cells. The adrenals of treated rats showed extensive hemorrhagic necrosis involving the zona reticularis by 2-3 days after treatment. Other organs affected by aflatoxin G₁-treated rats included the lungs and para-aortic lymph nodes. Aflatoxin G₁ did not produce liver lesions as did aflatoxin B₁.

ABSENCE OF AN EFFECT OF PARTIAL HEPATECTOMY ON AFLATOXIN B₁ CARCINOGENESIS. (E.)

ers, A. E. (Dept. Nutrition Food Science, Massachusetts Inst. Tech., Cambridge), N. S. Kula and P. Newberne. *Cancer Res* 31(5):491-495, 1971.

Fischer and Sprague-Dawley strain rats were given 375 µg aflatoxin B₁ (AFB) immediately, 24 hr, 48 hr, 6 days or 1 wk after partial hepatectomy; in 1 wk group, AFB was given prior to hepatectomy. Hepatectomy performed before or after AFB administration did not affect the incidence of hepatomas developed in treated rats compared to that in rats given AFB without hepatectomy. However, when AFB treatment was given 6 hr after either hepatectomy or sham operation the incidence of liver carcinomas was less than in rats given AFB beginning 24 hr or 6 days after hepatectomy or sham operation. Fischer rats seemed to be more sensitive to AFB carcinogenesis than were Sprague-Dawley rats.

THE CHANGING PATTERN OF CARCINOGENIC AMINOAZO DYE-BINDING PROTEINS DURING THE COURSE OF CONTINUOUS FEEDING OF 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. (E.) Sugimoto, T. (Fac. Science, U. Tokyo, Japan) and H. Terayama. *Chem-Biol Interact* 2(4):391-400, 1970.

Wistar rats fed a semisynthetic diet containing 0.06% 3'-methyl-4-dimethylaminoazobenzene and *ad lib* were sacrificed at 2 wk, 1, 3 or 10 weeks, and the livers were homogenized to provide liver sap for protein-bound dye and arginase assay. Protein content of the cell sap ranged from 15.7-27.1 mg/g liver; protein-bound dye range from 1.5-15.4 nmoles/g liver. The arginase content ranged from 164-346 U/g liver in azo dye fed animals compared to 5 control rats with 143 U/g and 3 hepatoma-bearing rats with 29 U/g. Throughout the study, the protein-bound dye as well as the arginase activity present in the liver cell sap was recovered almost completely in response to heat-treatment; the enzyme activity in livers of rats on continuous azo dye feeding proved to be rather labile, compared with activity noted in previous experiments with single doses, and was ultimately lost with subsequent chromatographic separation. As dye feeding progressed an increasingly retarded elution pattern

for basic protein fractions which was associated with more and more dye-binding was seen. Binding to the nonbasic proteins tended to decrease soon after the onset of dye-feeding.

2212 DNA OF RAT HEPATOMAS: SEARCH FOR GENE AMPLIFICATION. (E.) Shearer, R. W. (Dept. of Pathology, U. Wash., Seattle). *Biochem Biophys Res Commun* 43(6):1324-1328, 1971.

Differences between the DNAs of primary and transplantable rat hepatomas and normal rat liver kidney and lung tissues were investigated. Primary hepatomas DB-2E, DS-10B and DS-11D were induced in male rats by chronic feeding with a low riboflavin diet containing 0.06% 3'-methyl-dimethylaminoazobenzene. DB-2E grew in a Buffalo rat, while DS-10B and DS-11D grew in Sprague-Dawley rats. Tumor FS-1a was induced in the liver of a male Sprague-Dawley rat by chronic feeding of a normal diet plus 0.03% N-2-fluorenylacetamide. Isotope labeling of tumor cell RNA was done in cell culture (³H-uridine 20 µc/10⁶ cells added to the medium for 1 hr). No differences were detected in the rate or degree of annealing or in the shape of the melting curves of the hybrid molecules formed between hepatoma and normal DNAs; thus specific gene amplification was not characteristic for these tumors.

2213 BILE ACID INVOLVEMENT IN AZO DYE CARCINOGENESIS. (E.) Holland, J. C. (Dept. Biol. Sciences, Michigan Tech. U., Houghton) and J. D. Spain. *Cancer Res* 31(5):538-541, 1971.

Male rats were maintained on a diet containing 0.06% 3'-methyl-4-dimethylaminoazobenzene (3'MeDAB) for periods of 66 days; gas chromatography was used to identify bile acids in feces and urine. The feces of azo-dye-fed rats contained 7 bile acids, including lithocholic acid, deoxycholic acid, cholic acid and hyodeoxycholic acid. Deoxycholic acid was the prominent acid in the feces of rats on the carcinogenic diet. Of 112 rats given a normal diet, only 2 showed measurable quantities of bile acids; however, the urine of dye-fed rats showed significant amounts of cholic acid, hyodeoxycholic acid and ursodeoxycholic acid, these acids showing elevated assays in the urine of carcinogen-fed rats during the first 25 days of 3'MeDAB feeding. High assays of urinary bile acids in 3'MeDAB-fed rats seemed to correlate with high rates of proliferation of oval cells in the livers of the rats.

2214 COMPENSATORY HYPERTROPHY ASSOCIATED WITH THE PRESENCE OF A DAB TUMOR IN THE RAT. (Fr.) Boy, M. J. (Natl. Ctr. Sci. Res., Paris, France), A. Jacob, H. H. Phan, P. C. Quan and E. Le Breton. *C R Acad Sci* 272(16):2093-2096, 1971.

Sprague-Dawley rats with dimethylaminoazobenzene (DAB)-induced hepatomas arising as a result of a DAB-supplemented diet administered over 3 months showed

significantly greater hepatic compensatory hypertrophy than did control rats with no tumors. Weights of excised livers (weight of hepatomas excluded) in rats fed DAB were greater than weights of livers of untreated control rats. The mechanism of this hypertrophy may involve augmented NADPH and ATP formation associated with increased synthesis of protein and lipid in the tumor-bearing animals.

- 2215 THE EFFECT OF INGESTA UPON DIMETHYLHYDRAZINE INDUCED-CARCINOGENESIS IN RAT COLON. (Ger.) Wittig, G. (Inst. Cancer Res., German Acad. Sci., Berlin), G. P. Wildner and D. Ziebarth. *Arch Geschwulstforsch* 37(2):105-115, 1971.

N,N-Dimethylhydrazine dihydrochloride (DMH) (10 mg/kg/wk s.c.) was administered to intact control rats and to a second group with the colon isolated from ingesta by a double-orifice descending colostomy. A third group with colostomy but without DMH-treatment served as control. All received a standard diet *ad lib*. Colonic carcinomas, distal benign and malignant tumors developed in 6 to 7 months. The co-carcinogenic action of ingesta was indicated by the significant difference in localization and frequency of colon carcinoma between the colostomy and unoperated animals.

- 2216 INCREASED TRANSFER RIBONUCLEIC ACID METHYLASE ACTIVITY IN TUMOURS INDUCED IN THE MOUSE COLON BY THE ADMINISTRATION OF 1,2-DIMETHYLHYDRAZINE. (E.) Pegg, A. E. (Middlesex Hosp. Med. Sch., London, England) and A. Hawks. *Biochem J* 122(1):121-123, 1971.

Transfer RNA methylase activity was assayed in colonic and rectal tumors induced in NMRI mice by 10 and 15 mg s.c. injections of 1,2-dimethylhydrazine. Mice were given weekly injections, and the first tumors appeared after 24 wk of treatment. Tumors were anal, colonic or rectal squamous cell carcinomas. Methylation of tRNA was measured in the presence of 0.05 mg of tRNA from *E. coli* K12. After incubation, the incorporation of methyl groups into material insoluble in 5% (w/v) trichloroacetic acid was determined. Normal mouse colon incorporated 75-79 pmole of methyl groups/15 min/mg protein, while colonic tumors incorporated 214-228 pmole of methyl groups/15 min/mg protein.

- 2217 EFFECT OF STRESS ON THE ADRENOCORTICOLYTIC AND CARCINOGENIC ACTION OF 7,12-DIMETHYLBENZ(a)ANTHRACENE. (E.) Somogyi, A. (Inst. Med. Exp. Surg., U. Montreal, Quebec, Canada) and K. Kovacs. *Z Krebsforsch* 75(4):288-295, 1971.

Female rats were exposed to stress before and after administration of either 7,12-dimethylbenz(a)-anthracene (DMBA), or 7-hydroxymethyl-12-methylbenz(a)-anthracene (7-OHM-MBA). "Stress" consisted of forced muscular exercise lasting for 6.5 hr, or forced muscular restraint lasting for 17 hr.

Although stress did not increase the incidence of adrenal lesions in rats given 4 mg DMBA, it was found that lesions which did appear in rats undergoing exercise stress prior to DMBA treatment were more severe than those appearing in rats not subjected to stress. The adrenal necrotic effect produced by 7-OHM-MBA was also potentiated by stress. Adrenal lesion incidence increased in rats given 4 mg of DMBA and prior exercise stress compared to rats given DMBA and no stress. In rats given 2 mg DMBA and restraint stress, spirolactone treatment nearly abolished the aggravation by stress of DMBA adrenalcorticolysis, while spirolactone had no such effect in rats given 4 mg of DMBA and restraint. In turn, stress was able to counteract the adrenal protection from the effects of DMBA afforded by spirolactone. The mammary carcinogenic effect of DMBA was not affected by stress.

- 2218 7,12-DIMETHYLBENZ(a)ANTHRACENE AND HEPATOPLASIA IN REGENERATING RAT LIVER. (E.) Marquardt, H. (Sloan-Kettering Inst. for Cancer Res., New York, New York), S. S. Sternberg and F. S. Phillips. *Chem-Biol Interact* 2(4):401-403, 1971.

Male rats were given i.v. injections of 7,12-dimethylbenz(a)anthracene (DMBA, 25 mg/kg) following partial hepatectomy, and the ensuing tumor incidence was compared with that in rats given DMBA without hepatectomy, and with that in hepatectomized rats not given DMBA. Among hepatectomized rats not given DMBA, the numbers of animals surviving for 300 days after the beginning of the experiment were 19 out of 20 in the group given no treatment and 19 out of 20 in the group given an injection of a control emulsion. Among hepatectomized rats given DMBA and intact rats given DMBA the numbers surviving after 300 days were 9/20 and 7/20, resp. No hyperplastic hepatic nodules developed among rats not given DMBA, while among hepatectomized rats given DMBA, 8 of 20 animals developed hyperplastic nodules. None of the intact and DMBA-treated rats developed hyperplastic nodules. One hepatectomized and DMBA-treated rat out of 20 developed a hepatocellular carcinoma; no carcinomas developed in any of the other groups. Among nonhepatic changes observed in DMBA-treated rats (intact and hepatectomized) were squamous papillomas, leukemia, osteogenic carcinomas and nerve tumors.

- 2219 EFFECTS OF LOCAL X-RAY IRRADIATION ON 7,12-DIMETHYLBENZ(a)ANTHRACENE-INDUCED CARCINOGENESIS. (Rus.) Karnaukhova, E. N. (Inst. Exper. Clin. Oncol. Acad. Med. Sci., U.S.S.R., Moscow) and V. S. Turusov. *Med Radiol* 16(2):75-77, 1971.

Cutaneous administration of 2 drops/wk for 4 weeks of a solution of 7,12-dimethylbenz(a)anthracene (DMBA) (total dose of 100 µg) to the dorsal skin of male hybrid mice (C57Bl X CBA/F₁) followed by local x-ray

sure to 1000 r produced an intensification of the chemical carcinogenic process only during the initial 4 month period. At later experimental intervals, a synergistic effect was observed with 100 µg of DMBA only when the radiation exposure was decreased to 500 r, and after 8 months the combined effects slightly delayed the carcinogenesis compared to the controls. The average number of papillomas per animal was highest (3.3) when the DMBA was combined with a dose of 500 r, somewhat lower with only DMBA (3.0), and significantly lower when the carcinogen was combined with a radiation exposure to 1000 and 2000 r (1.8 and 1.6, resp.). When the same carcinogenic dose was administered alone for 6 weeks, 93% of the animals developed tumors compared to only 64-70% in the animals receiving both the carcinogen and subsequent irradiation. The average number of papillomas per animal, the total number of tumors, and the absolute number of animals with tumors was actually highest in the control group and decreased as the radiation dosage increased in the group receiving the combined effects.

2220 MORPHOLOGICAL AND BIOLOGICAL FEATURES OF EXPERIMENTAL TUMORS OF THE CEREBELLUM IN RATS. (Rus.) Yablonskaya, L. Ya. (Inst. Human Morphol. Acad. Med. Sci. U.S.S.R., Moscow) and N. A. Spryskova. *Arkhh Pat* 33(2):50-53, 1971.

A model of primary intracerebellar neurocytoma was obtained by implantation of a 2 mg tablet of 7,12-dimethylbenz(a)anthracene into the right hemisphere of the cerebellum of Wistar rats. After an average latency period of 238 days, 17 of 22 rats developed tumors of the following morphological types: 3 astrocytomas, 5 dedifferentiated astrocytomas, 1 polymorphous glioblastoma, 3 oligodendroglioblastomas, 3 glioblastomas of mixed structure and 2 arachnoid endotheliomas. Three transplantable lines were established from passages by the intracerebellar method; they included 1 protoplasmic astrocytoma (with low malignancy), 1 fibrillar protoplasmic astrocytoma, and 1 strain of polymorphous glioblastoma of the highest malignancy.

2221 AN EPOXIDE IS AN INTERMEDIATE IN THE MICRO-SOMAL METABOLISM OF THE CHEMICAL CARCINOGEN, DIBENZ(a,h)ANTHRACENE. (E.) Selkirk, J. K. (McArdle Lab. Cancer Res., U. Wisconsin, Madison), E. Huberman and C. Heidelberger. *Biochem Biophys Res Commun* 43(5):1010-1016, 1971.

Evidence that an epoxide is produced in the microsomal metabolism of dibenz(a,h)anthracene (DBA) was obtained by heating microsomes to inhibit epoxide hydrolase. Microsomes from livers of Charles River rats that had been pretreated with 1 mg of methylcholanthrene 3 days prior to sacrifice (to induce the hydroxylating enzymes) were heated for 5 min at 50°C and then incubated at room temperature for 30 sec with ³H-DBA, MgCl₂, NADPH and unlabeled DBA-5,6-epoxide. Incubation was terminated by the addition of ethyl acetate. Thin layer chromatography of the

organic layer of the incubation mixture revealed the presence of an epoxide, characterized by its kinetics of appearance and disappearance, by its behavior on TLC and by its conversion under acidic conditions to the corresponding phenol. The probable role of epoxides as the activated metabolic and the ultimate carcinogenic derivatives of methyl group-lacking carcinogenic hydrocarbons is discussed.

2222 GLUCOSE-6-PHOSPHATE DEHYDROGENASE AND LACTATE DEHYDROGENASE ISOENZYMES IN RODENT MAMMARY CARCINOMAS AND THE EFFECT OF OOPHORECTOMY. (E.) Richards, A. H. (U. Rochester School of Med. and Dentistry, New York) and R. Hilf. *Biochim Biophys Acta* 232(4):753-756, 1971.

Oophorectomy was performed on 7,12-dimethylbenz(a)-anthracene (DMBA)-induced mammary tumor-bearing Sprague-Dawley rats to ascertain whether the procedure would produce preferential effects on specific isoenzyme species. Rats were administered 5 mg DMBA/ml in sesame oil once a wk for 5 wk; tumors developed 8-12 wk after initial feeding of the carcinogen. The animals were then divided into groups according to approximate tumor size, and oophorectomy was performed under ether anesthesia; neoplasms were removed 3 or 5 days following oophorectomy for enzyme determinations. The average weights of the investigated tumors were: 1.5 g in intact rats, 2.2 g 3 days after oophorectomy and 2.4 g 5 days after oophorectomy. Glucose-6-phosphate dehydrogenase in the neoplasms was found to have 2 major isoenzymes, a fast-moving band designated as F, which constituted 85% of the total activity, and a slower-moving band designated as S. The activity levels of glucose-6-phosphate dehydrogenase were 8.6, 7.8 and 4 units per 100 mg at 0, 3 and 5 days after oophorectomy, resp. This decrease appeared to be due entirely to a decrease in the activity of glucose-6-phosphate dehydrogenase F, the hormonally responsive isoenzyme in these tumors. Lactate dehydrogenase activity decreased from 158 units (intact rats) to 131 units and 111 units per 100 mg 3 and 5 days following surgery. The isoenzymes lactate dehydrogenase-5 and -4 decreased from 1.4 units to 1.1 and 0.6 units and from 0.7 units to 0.4 and 0.4 units per mg DNA, resp., 3 and 5 days following surgery. These isoenzymes were of the muscle type, M₄ and M₃H₁ resp. The mammary carcinomas appeared to contain very low levels of the heart-type lactate dehydrogenase isoenzymes.

2223 HORMONE-INDUCED FUNCTIONAL RESPONSE IN MAMMARY GLANDS AND MAMMARY TUMOURS. (E.) Heise, E. (German Acad. Sci., Berlin-Buch, Germany), M. Görlich, Ch. Kleitke and G. Bacigalupo. *Europ J Cancer* 7(1):71-76, 1971.

Lactose was assayed in normal rat mammary glands, in mammary glands of rats given p.o. doses of 20 mg dimethylbenzanthracene (DMBA), and in hormone-stimulated mammary glands. Mammary glands of pregnant rats, transplanted fibroadenomata, and human mammary glands did not contain lactose. Lactose

was present in 2 of 24 DMBA-induced mammary carcinomas and in 5 of 33 DMBA-induced fibroadenomas. In rat mammary glands bearing DMBA-induced fibroadenomas, the content of lactose could be increased by treating the rats with hormones; 38.5% of rats bearing DMBA-induced fibroadenomas which were given testosterone treatment were lactose-positive in mammary tissue, 40.0% of tumor-bearing rats given estradiol had lactose, and 66.6% of tumor-bearing rats given estradiol-and-progesterone treatment had lactose-positive mammary tissue. Testosterone treatment induced lactose in normal mammary glands of pregnant rats, as did ovariectomy performed before parturition.

- 2224 BINDING OF [G-³H]-7,12-DIMETHYLBENZ(a)-ANTHRACENE TO DNA OF NORMAL AND OF RAPIDLY DIVIDING HEPATIC CELLS OF RATS. (E.) Marquardt, H. (McArdle Lab. Cancer Res., U. Wisconsin, Madison), A. Bendich, F. S. Philips and D. Hoffmann. *Chem Biol Interact* 3(1):1-11, 1971.

CD-line rats were injected i.v. at 24 hr after partial hepatectomy with ³H-7,12-dimethylbenz(a)anthracene (DMBA) in doses of 5 mC/120 µg/kg; they were killed 6 hr later, and the DNA isolated from regenerating liver had a specific activity after purification of 2 µC/g of DNA which represented binding of 2×10^{-10} moles of DMBA/g DNA or about 100 molecules of DMBA to the genome of one regenerating liver cell. The binding after 25 mg/kg i.v. was equivalent to 20,000 molecules of DMBA per liver cell genome. The binding of DMBA to DNA of regenerating rat liver and small intestine 1 hr after i.v. injection was negligible, but after 3 hr the binding to intestinal DNA was nearly maximal and that to regenerating liver DNA was about 50% of the maximum reached at 6 hr; this maximum was 4 times greater than that seen in intact liver of young adults. In the small intestine, the binding did not change appreciably between 6 and 48 hr, but in the regenerating liver the amount of DMBA bound to DNA dropped considerably between 6 and 24 hr. DNA isolated from regenerating liver 24 hr after partial hepatectomy bound about 2.5 times as much DMBA *in vitro* as that isolated from liver of young adults; prior activation of the DMBA did not seem to be required for tight binding under the conditions of this experiment. Gas chromatographic analysis of the DMBA-DNA complexes did not provide any evidence for the presence of covalent derivatives of DMBA.

- 2225 EFFECT OF POLYINOSINIC-POLYCYTIDYLIC ACID ON INDUCTION OF PRIMARY OR TRANSPLANTED TUMORS BY CHEMICAL CARCINOGEN OR IRRADIATION. (E.) Ball, J. K. (Cancer Res. Lab., U. Western Ontario, London, Ontario, Canada) and J. A. McCarter. *J Natl Cancer Inst* 46(5):1009-1014, 1971.

Mice of the CFW/D strain were given injections of polyinosinic-polycytidylic acid (poly I:C) 12-16 hr before a single neonatal injection of 25 µg of 7,12-dimethylbenz(a)anthracene (DMBA). Mice pretreated with poly I:C showed an increased mortality from thymic lymphomas compared to mice given DMBA

alone; by 150 days after treatment, all mice given DMBA and poly I:C had died with lymphomas, while 50% of mice given DMBA only survived. Poly I:C pretreatment reduced the incidence of thymic lymphomas induced by a neonatal exposure to 400 rads whole-body X-irradiation. Tumor incidence in mice exposed to X-irradiation and not treated with poly I:C was 94% while tumor incidence in mice pretreated with poly I:C and exposed to X-rays was 40%. Poly I:C treatment showed an antitumor effect on transplantation of thymic lymphomas when both tumor cells and poly I:C were administered i.p.; when poly I:C and tumor transplant cells were administered according to different protocols no antitumor protective influence was seen. In some cases, poly I:C appeared to enhance tumor development in mice given trans-

- 2226 REGRESSION OF PROLACTIN-DEPENDENT RAT MAMMARY CARCINOMA IN RESPONSE TO ANTIHORMONE TREATMENT. (E.) Butler, T. P. (Dept. Med., Case Western Reserve U. Sch. Med., Cleveland, Ohio) and O. H. Pearson. *Cancer Res* 31(6):817-820, 1971.

Mammary tumors were induced in female rats by intragastric administration of 7,12-dimethylbenz(a)anthracene (DMBA), and anti-prolactin antiserum was produced in rabbits using rat prolactin. Tumor-bearing rats were given s.c. or i.p. injections of anti-prolactin antiserum twice daily for 36 days (1 ml of 1/12,000 titer antiserum daily for 13 days, 0.5 ml of 1/32,000 titer antiserum daily for 19 days and 0.4 ml of 1/64,000 titer antiserum daily for 4 days). Fifty percent of the tumors in anti-prolactin-treated rats and 13% of the tumors in rats given normal rabbit serum regressed. Thirty-five percent of the tumors in anti-prolactin-treated rats and 57% of the tumors in untreated rats grew. Tumors in treated rats resumed growth after anti-hormone treatment had been discontinued. After 36 days of treatment tumor areas in untreated rats amounted to more than 6 cm² compared to tumor areas in anti-hormone treated rats of about 3 cm².

- 2227 MAST CELLS IN THE 7,12-DIMETHYLBENZ(a)-ANTHRACENE INDUCED MAMMARY TUMORS IN RATS. (Ger.) Kovacs, K. (Inst. Exp. Med. Surg., U. Mo. Canada) and A. Somogyi. *Zbl allg Path* 114(1):69-71, 1971.

The effect of 7,12-dimethylbenz(a)anthracene (DMBA) on the accumulation of mast cells was investigated before and after tumor induction. In the untreated animals, the few mast cells present were distributed in the tubules and alveoli of the mammary glands in the fat and connective tissue at times. Four days after the administration of a single dose of DMBA by gavage, mast cells were found to be slightly increased in number and were distributed similarly to the untreated animals. Not all the animals receiving the DMBA tumors. The number of mast cells in those tumors that developed 2-3 months after DMBA varied and was very abundant in some, while in others there were only slightly more mast cells than were found in

treated animals; they occurred mainly in the connective tissue and were unevenly distributed. Triclinolone, compound 48/80 and polymyxin, each administered repeatedly for 2-3 months after DMBA-induced tumors occurred, caused a reduction in the number of mast cells. The role of these cells in carcinogenesis is not known.

8 CARCINOGENICITY OF AIRPLANE ENGINE SOOT IN EXPERIMENTAL ANIMALS. (Rus.) Linnik, A. (Inst. Exp. Clinical Oncol. Acad. Med. Sci., Moscow, U.S.S.R.), G. A. Smirnov and L. M. Shabad. *Bull Eksp Biol Med* 71(2):83-87, 1971.

Extracts of soot from airplane turbines and pistons containing benzo(a)pyrene concentrations of 25 mg/kg and 30 mg/kg, resp., applied twice a wk for 1 month and then 3 times/wk for a total of 50 applications to the interscapular region of the skin of 1st generation hybrid mice (C57 X CBA), produced tumors in 58 of the 66 treated animals; 28 of 34 control animals treated similarly with a 0.1% solution of benzo(a)pyrene also developed neoplasms; a fourth group of 20 mice received pure benzene and did not develop any neoplasms. Histologically, confirmed squamous cell carcinoma of the skin developed in 52 of the 58 animals, sarcoma in 1 mouse and carcinoma in 4 mice; lymph node cancer metastasis was observed in 6 cases. The results suggest that benzo(a)pyrene concentration may serve as an indicator of the carcinogenic potency of soot and similar products.

9 IN VITRO CELLULAR UPTAKE OF BENZO(a)PYRENE MEASURED BY A MICROFLUOROMETRIC TECHNIQUE. Kouri, R. E. (Roche Inst. Molec. Biol., Nutley, N.J.), R. A. Lubet and D. Q. Brown. *Proc Soc Exp Biol Med* 136(4):1038-1044, 1971.

Cell line derived from lung tissue of the Chinese hamster was incubated with 0.05% of benzo(a)pyrene and BP uptake was measured by a microfluorometric technique. Cells that were pretreated with 0.6 µg/ml BP for 12 hr and incubated for 1 hr without BP prior to toxicity experiments showed an increase in uptake of BP at 0.5, 3.0, 5.0, 11.0 and 24.0 hr periods compared to non-pretreated cells. The ability to uptake the chemical was correlated with its induced toxicity. A lysosomal extrusion process appeared to be operative at low concentrations of BP.

EFFECT OF OZONE ON BENZOPYRENE HYDROXYLASE ACTIVITY IN THE SYRIAN GOLDEN HAMSTER. Palmer, M. S. (Environmental Protection Agency, Air Pollution Control Off., Div. Hlth. Effects Res., Cincinnati, O.), D. H. Swanson and J. Coffin. *Cancer Res* 31(6):730-733, 1971.

Animals of both sexes were exposed to ozone for 3 weeks after which benzo(a)pyrene (BP) hydroxylase activity in the lungs of exposed animals was determined. In hamsters not exposed to ozone, the

BP hydroxylase activity in the lung was 0.09 U of enzyme activity/mg wet weight of tissue; in animals exposed to 1,470 µg/m³ of ozone, enzyme activity was 0.06 U/mg, and in animals exposed to 5,880 and 19,600 µg/m³ of ozone, enzyme activity was 0.03 U/mg. Exposure to ozone did not affect BP hydroxylase activity in the liver of hamsters. When hamsters were pretreated with 10 mg BP prior to ozone exposure, lung BP hydroxylase activity was increased by as much as 70-fold; however, values for enzyme activity were still significantly lower in ozone-treated hamsters than in controls. Lungs of hamsters given BP and not exposed to ozone showed 6.6 U enzyme activity/mg tissue assayed, while hamsters given pretreatment and 1,470 µg/m³ ozone showed 4.3 U/mg. Hamsters given BP pretreatment and 5,880 µg/m³ ozone showed 1.8 U/mg BP hydroxylase activity. It was thought that ozone acted to delay the enzymatic transformation of inhaled BP, thus functioning as a cocarcinogen for this agent.

2231 TRANSPLACENTAL ACTION OF BENZ(A)PYRENE AND PYRENE IN MOUSE EMBRYO KIDNEY TISSUE CULTURES. (Rus.) Sorokina, Yu. D. (Inst. Exp. Clin. Oncol. Acad. Med. Sci. U.S.S.R., Moscow). *Bull Eksp Biol Med* 71(3):72-76, 1971.

The transplacental action of benzo(a)pyrene (BP) in (C57BLxCBA)F₁ mouse embryo kidney tissue cultures was investigated. BP or pyrene (P) were administered (1 mg in olive oil 4 times, i.m.) during the last wk of pregnancy and embryo explants were taken on the 20-21st day of pregnancy. The survival time of tissue cultures from both experimental groups appeared to be higher than that of the untreated explants. Ninety-eight percent of the untreated embryo, 54% of the P-treated and 47% of the BP-treated embryo tissue cultures were depleted 22 days after the explant. The hyperplastic alterations consisted of minor epithelial atypia and constituted 1.8% of the total number of control explants. A considerably higher degree of atypia within the hyperplastic alterations (18.0% in the P-treated and 27% in the BP-treated embryo tissues) along with hyperplasia of isolated canaliculi and structureless epithelial blast cells were observed in the treated embryo tissues. Diffuse epithelial hyperplasia, partial or total disappearance of canalicular structure and the formation of blast cells were observed in 9 (75%) of the BP-treated explants on the 22nd-30th day after explant. Such effects were not seen in the P-treated explants.

2232 THE USE OF FREUND'S ADJUVANT IN THE PRE-CANCEROUS STAGE: ITS EFFECT ON CHEMICAL CARCINOGENESIS. (Rus.) Volegov, A. I. (P. A. Herzen Sci. Res. Inst. Oncol., U.S.S.R., Moscow). *Bull Eksp Biol Med* 71(2):79-81, 1971.

Freund's complete adjuvant (FA) administered into the pad of the left paw in 16 Wistar rats (0.03 ml) 80 days following the s.c. administration of 3 mg of 3-methylcholanthrene (MC) reduced the resistance of the animals to the carcinogenic effect of the com-

pound. Histologically confirmed polymorphocellular sarcoma developed in the FA + MC-treated rats; in control rats without FA treatment, MC induced only spindle or polymorphic cells. A third group of rats administered 0.03 ml of Freund's adjuvant s.c. into the abdominal region had neoplasms of an intermediate grade of malignancy. The first neoplasms appeared 3½ months after administration of the carcinogen; animals receiving the adjuvant in the paw had a significantly higher incidence of tumors at 5½ months; however, at all other experimental times, there were no significant differences among the 3 groups. FA induced polyarthritis only in 8 of the 16 rats receiving the paw injection; however, no correlation could be observed between the appearance of the polyarthritis and the decreased resistance to the oncologic process. The effect of FA seemed to be associated with the development of an autoimmune process in the organism of the animals.

- 2233 THE EFFECT OF ERYTHROPOIETIN ON THE DEVELOPMENT OF 20-METHYLCHOLANTHRENE-INDUCED SKIN TUMORS. (Rus.) Finogenova, M. A. (Inst. Nutr. Acad. Med. Sci. U.S.S.R., Moscow). *Pat Fiziol Exp Ter* 15(1):41-45, 1971.

The effect of erythropoietin-containing serum (EPS) on the development of skin tumors induced by 3-methylcholanthrene (MC) was studied in CBAXC57BL male and female mice. MC was applied topically (0.02 ml as a 0.05% benzene soln) in the intercostal region and EPS, obtained from rando-bred rats, was administered simultaneously (0.5 ml/EPS, i.p.) once a wk for 5 wks; another group received additionally for 5 more wk a double dose of EPS. A second series of experiments was carried out in mice treated with a 1% croton oil in benzene soln (0.02 ml once a wk for 20 wk), starting 2 wk after a single dose (0.04 ml) of MC application; various groups received 1 ml EPS the day before, the day of and the day after MC or croton oil application. In a third series MC (0.02 ml single dose) application was followed 30 days later by 1% croton oil treatment (0.02 ml once a wk) through the 20th wk of the experiment; EPS was given (1 ml i.p. once in 5 days) for 30 days after the MC application. EPS decreased the latency period for MC induction of the 1st papilloma by 3 wk, (from wk 11 to wk 8) and the development of malignancy by 2 wk (from wk 20 to wk 18) compared to the mice receiving normal serum within the first series of experiments; additional EPS treatment decreased the latency for the occurrence of the first papilloma and the development of the first malignancy by 1 wk only. EPS treatment increased the number of animals with papillomas by 23% on the 14th wk and by 29% on the 20th wk and had no effect on the latency period in the second experimental series (1% croton oil, MC and 3 doses of EPS). The incidence of papillomas was increased by 23-30% in the third experimental series (1% croton oil, MC and 6 doses of EPS), while the occurrence of the 1st papilloma and the malignization were hastened by 2 wk. The enhancing effects of EPS appeared to be more manifest during the early stages of carcinogenesis with or without cocarcinogen; its effects

appeared to be minor during the activation stage and stronger in females.

- 2234 THE EFFECT OF VITAMIN B₁₂ ON THE INDUCTION OF SKIN TUMORS IN MICE. (Rus.) Ostryanina, A. D. (Inst. Nutr. Acad. Med. Sci. U.S.S.R., Moscow). *Pat Fiziol Exp Ter* 15(1):48-51, 1971.

The effect of vitamin B₁₂ on 3-methylcholanthrene (MC) skin carcinogenesis was studied in 807 CBAXC57BL male mice. MC was applied topically to the intercostal region as a 0.05% benzene soln once a wk for 12-24 wks. Vitamin B₁₂ was administered s.c. (20, 40 or 200 µg/kg) 3 times a wk as follows: I) 4 wk before MC treatment, II) 4 wk before and during MC treatment up to the development of the papilloma (10 wk), III) during the MC treatment for 10 wk, IV) as in III with 2 wk intervals after each month, or V) after the occurrence of the 1st papilloma (following 12 wk of MC treatment) for 1 or 12 wk. An enhancement of carcinogenesis was seen when vitamin B₁₂ treatment was started simultaneously with MC application (III). The 20 or 40 µg/kg dose of vitamin B₁₂ reduced the latency period by 1 wk and the 200 µg/kg dose reduced the latency by 2 wks. Similar results were noticed in the enhancement of malignant transformation of the papillomas. When given after the occurrence of the 1st tumor (V) or during the MC treatment with 2 wk intervals (IV), vitamin B₁₂ doses of 20 and 40 µg/kg produced a marked enhancement of malignant transformation. No effects were seen, however, when the vitamin was administered prior to and/or continuously during the period of MC application (I, II); this may be due to a state of vitamin B₁₂ saturation.

- 2235 THE INFLUENCE OF MUCOUS SECRETION ON THE INDUCTION OF UTERINE CERVICAL CARCINOMA IN MICE OF THE STRAINS BN, PORTON AND A. (E.) Gorski, T. (Inst. Oncol., Gliwice, Poland) and W. Smieciński. *Folia Biol* 17(1):75-82, 1969.

Pellets of beeswax impregnated with methylcholanthrene (MC) were placed intravaginally in mice of strains A, Porton and BN. In some mice, a ligature was placed in the vagina below the MC pellet resulting in an increase in mucous moistening; in other mice the ligature was placed in the vagina above the pellet resulting in a decrease in mucous moistening. In BN and Porton mice treated with MC the incidence of cervical carcinoma was lower in controls with vaginal ligature than in mice with ligatures; carcinoma incidence was higher in mice with ligatures above the MC and also higher in mice with ligatures below the pellet. However, in mice of strain A with the ligature placed above the pellet, carcinoma incidence was lower than in MC-treated mice without ligatures.

- 2236 CHROMOSOMES OF CHEMICALLY INDUCED TUMORS AFTER TUMOUR POLYPASSAGE. (E.) Popescu, N. C. (Acad. Med. Sci., Bucharest, Romania) and I. Cioloca. *Neoplasma* 18(1):15-18, 1971.

tumors induced in hamsters by 3-methylcholanthrene were implanted s.c. into recipient hamsters 6 times at 48 hr intervals; after 6 transplantations the tumor fragments were allowed to grow for 14 days and then analyzed chromosomally. Cells from tumors which had been repeatedly transplanted to a host designated "polypassaged" tumor cells) were predominantly diploid; on the other hand, tumors which had not been polypassaged were predominantly tetraploid. Tumors were originally induced in male hamsters, and polypassaged in female hamsters, and the percentage of host cells with female karyotypes in polypassaged tumors was 33-40%.

237 CHEMICAL AND ENZYMIC COMPOSITION OF MICROSOMAL SUBFRACTIONS FROM RAT LIVER AFTER TREATMENT WITH PHENOBARBITAL AND 3-METHYLCHOLANTHRENE. (E.) Glaumann, H. (Karolinska Inst., Stockholm, Sweden). *Chem-Biol Interact* 2(4):369-380, 1970.

Phenobarbital (8 mg/100 g body wt) once daily for 5 days and 3-methylcholanthrene (2 mg/100 g) on day 4 and 2 prior to the experiment were administered i.p. to starved adult male albino rats and the distribution of protein, RNA, phospholipids and cholesterol was determined among microsomal subfractions of rough, smooth I and smooth II membranes. Phenobarbital increased the protein, phospholipid and cholesterol content in total, rough, and in smooth I subfractions in particular. No increase in either protein or lipids of the smooth II microsomes was seen, and although there were quantitative differences, the response in the rough subfraction paralleled that in smooth I membranes. In contrast, 3-methylcholanthrene did not enhance the content of either protein or lipids in any of the microsomal subfractions. Phenobarbital caused some decrease in the activities of glucose-6-phosphatase, ATPase, and AMPase recovered from total, rough and smooth I microsomes and increased nucleoside diphosphatases in these same fractions; 3-methylcholanthrene failed to change these activities except for a moderate increase in nucleoside diphosphatase activity in the rough and smooth I microsomes.

238 THE INFLUENCE OF BCG VACCINE AND GROWTH OF METHYLCHOLANTHRENE-INDUCED TUMOR ON THE STRUCTURE OF THE RETICULO-HISTIOCYTE SYSTEM OF LIVER AND SPLEEN IN RATS AND MICE. (Ger.) Wolf, G. (Inst. Cancer Res., German Acad. Sci., Berlin), N. Schremmer and K. H. Horn. *Arch Geschwulstforsch* 37(2):152-160, 1971.

Transplantation of methylcholanthrene-induced tumor tissue into 3-month-old male and female rats was followed by significant hyperplastic changes in the liver and spleen within 5-13 days. S. C. injection of BCG vaccine either concomitantly with or 14 days preceding tumor transplants did not affect these changes; nor did BCG vaccine alone have any demonstrable morphologic effect on these 2 organs. Tissue changes were examined under light and electron microscopy; splenic lympho-reticular structure hyperplasia and enlargement of Kupffer cells were observed.

2239 CARCINOGENIC ACTION OF NITROSAMINES IN MICE. (Rus.) Shabad, L. M. (Inst. Exp. Clin. Oncol. Acad. Med. Sci. U.S.S.R., Moscow) and L. A. Savluchinskaya. *Biull Eksp Biol Med* 71(3):76-78, 1971.

The effect of dimethylnitrosamine (DMNA), diethylnitrosamine (DENA) and nitrosomethylurea (NMU) in 104 (54 male and 50 female) A and 117 (67 male and 50 female) C3HA mice, 2-months-old, was investigated. The carcinogens (0.1 mg) were administered s.c. twice a wk for 3 wk each or p.o. 3 times a wk for 8-12 wk. The first tumor (adenocarcinoma of the lung) was noticed in a C3HA mouse 12 months after s.c. treatment and 7 months after p.o. treatment (adenoma of the lung). Lung and liver appeared to be the main target organs. The adenomas of the lung were usually multiple and of the mixed type with a well differentiated core and the cells contained hyperchromic oval nuclei. The liver tumors appeared to be benign (simple or multiple) with large cells and hyperchromic nuclei; 9 mice had hepatocellular malignancies with infiltrative growth and polymorphic cells. DENA induced the highest number of malignancies of the cardia (10 of 34 C3HA mice); DMNA induced cystadenomas of the kidney in 7 of 54 C3HA mice and 1 giant adenoma (kidney in 1 animal). The cystadenomas appeared to be a third stage of transformation after hyperplasia and focal proliferation that developed into adenocarcinoma or cystadenocarcinoma. The highest incidence of tumors was induced by NMU (58-92%); the incidence of tumors in the overall experiment was 34-93%. There was no difference in susceptibility of the 2 strains A and C3HA towards DMNA or NMU; the C3HA strain seemed to be somewhat more susceptible to DENA, and 29% of them developed malignancies of the cardia. No substantial differences between the action of the 3 carcinogens were observed, however.

2240 TOXICITY OF DIMETHYLNITROSAMINE FOR THE RAT TESTIS. (E.) Hard, G. C. (Med. Res. Counc. Lab., Carshalton, Surrey, England) and W. H. Butler. *J Path* 102(4):201-207, 1970.

Male rats were maintained on a protein-supplemented or a protein-free diet and were given a single i.p. injection of either 30 or 60 mg/kg of dimethylnitrosamine (DMN); the effects of DMN on testicular tissue were observed in the 2 dietary groups. Rats given 60 mg/kg DMN and maintained on a protein-free diet showed degenerate changes in the spermatids of many testicular tubules. Twenty-four hours after injection occasional multinucleate giant cells containing nuclei of spermatid origin were seen. Degenerative changes progressed during the next few days, involving spermatocytes and spermatogonia; by the second day, all tubules were uniformly affected. Spermatids at this stage showed karyorrhexis, karyolysis or pyknosis of nuclei. At 4 days spermatozoa were absent and spermatocytes were rare. The peak of degenerative change was seen at 7 days; after 2 wk, most rats showed progressive regeneration of seminiferous epithelium, and multinucleate cells had disappeared. By 4 wk, spermatogenesis was largely restored. In rats given 60 mg/kg DMN and

maintained on a protein-supplemented diet, changes were less pronounced than in the protein-free dietary group. Thirty mg/kg DMN produced less marked changes in rats given a protein-free diet than did 60 mg/kg. The testes of rats given 30 mg DMN and a protein-supplemented diet showed no significant changes.

- 2241 NITROSAMINE STUDIES: INDUCTION OF LUNG ADENOMAS BY CONCURRENT ADMINISTRATION OF SODIUM NITRITE AND SECONDARY AMINES IN SWISS MICE. (E.) Greenblatt, M. (U. Nebraska Coll. Med., Omaha), S. Mirvish and B. T. So. *J Nat Cancer Inst* 46(5):1029-1034, 1971.

Swiss strain mice were maintained for 40 wk on a diet containing one of the following chemicals: piperazine (6.25 g/kg of food), morpholine (6.33 g/kg food), N-methylaniline (1.95 g/kg food), dinitrosopiperazine (40 mg/liter of drinking water), dimethylamine hydrochloride (5.9 g/kg food), nitrosomorpholine (80 mg/liter water), dimethylnitrosamine (10 mg/liter water) or N-nitroso-N-methylaniline (70 mg/liter water). Chemicals were administered with sodium nitrite (1 g/liter) in drinking water. Piperazine, morpholine and N-methylaniline increased the incidence of lung adenomas, especially in male mice. Dinitrosopiperazine, nitrosomorpholine, dimethylnitrosamine and N-nitroso-N-methylaniline produced a 10-30-fold increase in lung adenomas in treated as compared to untreated mice. Neither dimethylamine hydrochloride nor sodium nitrite alone nor secondary amines alone caused an increase in tumor incidence.

- 2242 DIETHYLNITROSAMINE-INDUCED ALTERATIONS IN THE TRACHEOBRONCHIAL SYSTEM OF SYRIAN GOLDEN HAMSTERS. (E.) Althoff, J. (U. Nebraska Med. Ctr., Omaha), R. Wilson and U. Mohr. *J Nat Cancer Inst* 46(5):1067-1071, 1971.

Ten male and 10 female golden hamsters were given s.c. injections of 10 mg/kg diethylnitrosamine and the ensuing changes in the tracheobronchial system were observed under an electron microscope. Papillary tumors developed in all hamsters given the carcinogen. Prior to the development of papillary tumors, hyperplasia and dysplasia were seen in epithelial tissue; tumor epithelium also showed hyperplasia and dysplasia. Squamous epithelium showed no metaplastic change, either in the tracheobronchial tissue or in tumor epithelium.

- 2243 CYTOGENETIC STUDIES IN SPRAGUE-DAWLEY RATS DURING THE ADMINISTRATION OF A CARCINOGENIC NITROSO COMPOUND--DIETHYLNITROSAMINE. (E.) Grover, S. (Med. Coll., Nagpur, India) and P. Fischer. *Europ J Cancer* 7(1):77-82, 1971.

Newborn rats were given daily s.c. injections of diethylnitrosamine (DEN), in a dose of 10 mg/kg of body wt, for up to 48 days. Cytogenetic studies

were performed on liver and spleen cells from treated animals. Until day 3 of carcinogen treatment, karyotypes from spleens and livers of treated rats did not differ from those of untreated rats. On day 3, however, 9 of 126 metaphases studied were pseudodiploid with a small metacentric or submetacentric chromosome and an increased number of small acrocentric chromosomes. By day 48 of DEN treatment, liver cell chromosomes were sticky and elongated with a tendency to non-disjunction and fusion. Of 4 karyotypes from this material showed a missing A7 chromosome and an extra small acrocentric. Nodules were found on livers of rats sacrificed after 60 days on the carcinogenic regimen, and karyotypes of cells from these nodules showed similar patterns to karyotypes of cells from rats treated with carcinogen for 48 days.

- 2244 DIFFERENCE IN THE ONCOGENICITY OF N-METHYL-N-NITROSO- β -D-GLUCOSYLAMINE, N-METHYL-N-NITROSO- β -D-GALACTOSYLAMINE AND ANALOGOUS SUGAR ALCOHOLS IN RATS. (Ger.) Güttner, J. (Central Inst. Microbiol and Exp. Ther., Jena, Germany), A. Schmidt and W. Jungst. *Z Krebsforsch* 75(4):296-300, 1971.

Four groups of 10-13 wk-old Wistar rats (4 males and 4 females each) were administered p.o. 50, 460, or 1800 mg/kg of N-methyl-N-nitroso- β -D-glucosylamine or alcohol analog and 24 animals (males or females) were given 750 mg/kg N-methyl-N-nitroso- β -D-galactosylamine or alcohol analog twice weekly for 25 wk. Both MN-glucosylamine and its alcohol analog induced hepatomas (in 10 and 9 rats, resp.) and phrenic ampulla papillomas (in 12 and 13 rats, resp.). No significant differences in their effects due to the different dosages were seen. The alcohol analog induced additional tumors of the larynx, pharynx and esophagus in 21 rats. The total MN-glucosylamine induced tumor incidence was 58% and that induced by its alcohol analog was 91%. MN-galactosylamine and its alcohol analog induced no histologically detectable tumors through the 322nd day of the experimental period.

- 2245 STIMULATION OF THE RATE OF INDUCTION OF LUNG TUMORS BY DIETHYLNITROSAMINE IN MICE. (Ger.) Hilfrich, J. (Path. Dept., U. Hamburg Med. Sch., Germany), J. Althoff and U. Mohr. *Krebsforsch* 75(3):240-242, 1970.

Administration of 50 mg/kg of diethylnitrosamine s.c. once or twice weekly for 4 wk (total dose of 200 or 400 mg/kg, resp.) to male and female mice elicited a 2-3-fold increase over controls in rate of lung adenoma formation with significant decreased latency periods within 6-12 months of treatment. Although there was a 60% mortality with marked hepatic damage after 2 months at the higher dose level, no significant difference in tumor formation was found between the 2 dosage groups. Hepatomas, papillomas of the forestomach and squamous cell carcinoma of the nasopharyngeal cavity were also observed in diethylnitrosamine-treated animals.

46 STUDIES ON LUNG TUMOURS: II. MORPHOLOGICAL ALTERATIONS INDUCED BY DIMETHYLNITROSAMINE IN MOUSE LUNG AND LIVER AND THEIR RELEVANCE TO CARCINOGENESIS. (E.) Calafat, J. (The Netherlands Cancer Inst., Amsterdam), L. den Engelse and P. Melot. *Chem-Biol Interact* 2(4):309-320, 1970.

Ultrastructural changes in the livers and lungs of C57BL/6 and C3Hf mice given a single i.p. injection of 10 mg/kg dimethylnitrosamine (DMNA) were observed 24 hr after administration of the carcinogen. DMNA produced similar changes in both mouse strains. Cytoplasmic changes were first seen in liver cells, and nuclear changes were seen first in lung cells. 24 hr after treatment, the endoplasmic reticulum in bronchiolar epithelial lung cells showed a concentric arrangement surrounding 1 or more mitochondria. In the nuclei of some liver cells, dark plaques were seen 1 hr after injection. By 2.4 hr, nucleolar components were arranged into a fibrillar zone, a smaller granular zone and a dark peripheral zone. The peripheral dark zone and plaques were similar to inclusions seen after treatment of mice with 4-nitroquinoline-N-oxide, lasiocarpine or aflatoxin. EDTA staining suggested that the dark-staining components of the nucleolus were composed of protein. Nucleolar components were also rearranged in the bronchiolar epithelium of lungs of DMNA-treated mice. These results did not reveal a clear relationship between the morphological and carcinogenic effects of DMNA in the lung or liver of the mouse.

47 HISTOCHEMICAL ACTIVITY OF ALKALINE AND ACID NUCLEASES IN THE RAT LIVER PARENCHYMA DURING N-NITROSOMORPHOLINE CARCINOGENESIS. (E.) Ober, H. S. (Dept. Gen. Path., U. Louvain, Belgium), Fort and J.-M. Brucher. *Cancer Res* 31(6):913-916, 1971.

Young male albino rats were given 8 mg/kg N-nitrosomorpholine by intragastric intubation 5 times daily, and the localization in the liver of alkaline and acid DNase and RNase was observed. In rats killed after 38 days on the carcinogenic regimen, levels of acid and alkaline nucleases were nearly normal in the liver. After 59 days of treatment, large areas of liver parenchyma cells with clear cytoplasmic vacuoles could be seen; acid nuclease activity was markedly decreased in some groups of liver cells, while alkaline nuclease activity was only slightly reduced. By 78-85 days of carcinogen treatment, macroscopic nodules had begun to appear in the livers of treated rats; these nodules had distinctly reduced acid and alkaline nucleases. By 100 days of carcinogen treatment, the nodules had enlarged and acid nuclease activity in them was practically nil. However, acid nuclease was present in the surrounding liver parenchyma cells. Alkaline nuclease was also nearly absent in the nodules and present in surrounding parenchyma cells. By 134 days of treatment, signs of malignant transformation were present in livers; areas of malignancy revealed acid or alkaline DNase or RNase. However, intense nuclease activity was seen in the peripheral zones of necrotic foci.

2248 QUANTITATIVE ASPECTS OF THE REPAIR OF ALKYLATED DNA IN CULTURED MAMMALIAN CELLS: I. THE EFFECT ON HeLa AND CHINESE HAMSTER CELL SURVIVAL OF ALKYLATION OF CELLULAR MACRO-MOLECULES. (E.) Roberts, J. J. (Roy. Cancer Hosp., London, England), J. M. Pascoe, J. E. Plant, J. E. Sturrock and A. R. Crathorn. *Chem Biol Interact* 3(1):29-47, 1971.

Single cell suspension cultures of HeLa S3, a human female tumor line, and Chinese hamster V79-379A cells were treated with varying concentrations of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), N-methyl-N-nitrosourea (MNU), methyl methanesulphonate (MMS), mustard gas or half mustard gas for 1 hr. Concentrations of MNNG, MNU, and MMS required to kill 90% of the HeLa cells were in the ratio of 1:200:2000, while for hamster cells the corresponding ratios were 1:100:150. Ion-exchange chromatography for acid-hydrolyzed DNA from both cell lines with labeled MNNG, MNU and MMS indicated that virtually all the radioactivity eluted from the column was associated with the absorbance corresponding to 7-methylguanine, and there was no evidence for metabolic incorporation of radioactivity into the purines. A clear linear relationship existed between the reaction of hamster cell DNA with the alkylating agents and the concentration of the three agents. Treatment of HeLa cells with the MNU and the MNNG showed that for a given toxicity the binding of alkylating agent to DNA was very much less than predicted with a non-linear relationship of the dose-binding curves; with HeLa cells and MMS results similar to those seen in hamster cells were obtained; reactions of MNNG and MNU with RNA revealed similar behavior. Methylation of either protein or RNA molecules is unlikely to be responsible for the cytotoxic effect of these agents.

2249 DISTRIBUTION OF N-[¹⁴C] METHYL-N-NITROSOUREA IN THE RAT AFTER SYSTEMIC ADMINISTRATION. (Ger.) Kleihues, P. (Max-Planck Inst., Cologne-Merheim, Germany) and K. Patzschke. *Z Krebsforsch* 75(3):193-200, 1971.

The distribution of N-¹⁴C-methyl-N-nitrosourea in the rat was investigated by total body autoradiography 2 min after i.v. administration of 100 mg/kg of the compound. The lowest level of activity was found in the bones and adipose tissue. The concentration of label was greater in muscle cells, especially in the tongue and neck. Highest activity was found in the liver, kidney, parotid gland, pancreas and spleen. The stomach and intestinal walls were also labeled. In the central nervous system, the cerebrum, the spinal cord, the cerebellum, the brain stem, and hypophysis were labeled in varying degrees; no activity was demonstrable in the subarachnoid space or in the basal cisterns.

2250 THE RESPONSE OF CHINESE HAMSTER CELLS TO N-METHYL-N'-NITRO-N-NITROSOGUANIDINE. (E.) Barranco, S. C. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston) and R. M. Humphrey. *Mutat Res* 11(4):421-429, 1971.

Synchronized Chinese hamster embryo cells in culture were treated with up to 5 µg/ml culture fluid of

N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) for 30 min; about 97% of treated cells failed to survive the minimal 0.5 µg/ml dose of MNNG when the treated cells were asynchronous. While cell survival was usually less than 1%, it was lowest (0.04%) in cells treated with MNNG during the G₁/S mitotic phase transition. When cells in the early S-phase were treated with MNNG it was found that the percentage of cells labeled with ³H-thymidine reached 92% by 3-4 hr after release of the synchronizing mitosis block, then fell to 31% by 7 hr and rose to 80% by 13 hr. Treatment with MNNG did not hinder the progression of cells from early S-phase to the G₂-phase. Treatment of cells in the G₂-phase with MNNG, however, did delay the progression of cells from this phase. When cells in mitosis were treated with MNNG it was found that untreated cells progressed out of mitosis and into G₁ in 1 hr with 0% mitotic index, the MNNG-treated cells however plateaued at 70% mitotic index for 2 hr.

- 2251 SOME CONTRIBUTIONS TO THE INFLUENCE OF THE AUTONOMIC NERVOUS SYSTEM ON THE EXPERIMENTAL INDUCTION OF CANCER OF THE STOMACH. (E.) Mizukami, T. (2nd Surg. Clin., Kanazawa U., Japan), O. Takamatsu and K. Miwa. *Neoplasma* 17(6):649-654, 1970.

Male rats were laparotomized and divided into 3 experimental groups; group I was vagotomized and given N-methyl-N'-nitro-N-nitrosoguanidine (NG, 50 mg/l water), group II was splanchnicotomized and given NG, and group III underwent no further surgery and was given NG. By 50 wk after treatment, 31% of controls had developed tumors of the glandular stomach, 59% of vagotomized rats had developed tumors and 22% of splanchnicotomized rats had developed tumors. More lethal cases of stomach cancer occurred in vagotomized rats than in splanchnicotomized rats. Surgical blockade of the vegetative nervous system, however, did not affect NG-induced stomach cancer incidence. It was suggested that vagotomy for peptic ulcer may entail an increased risk of developing cancer of the glandular stomach.

- 2252 STOMACH CANCER AND NEUROGENIC TUMORS INDUCED BY ORAL ADMINISTRATION OF METHYL-NITROSOBIURET (MNB) IN RATS. (Ger.) Druckrey, H. (Div. Prev. Med., Max-Planck-Inst., Freiburg, Germany), C. Landschütz, R. Preussmann and S. Ivankovic. *Z Krebsforsch* 75(3):229-239, 1971.

Chronic treatment with methyl-nitrosobiuret (MNB) of BD rats (5 mg/kg in the drinking water, stabilized with a phosphate buffer at pH 6, 5 times per wk for 378 days) induced gastric adenocarcinoma in 7 and brain tumors in 2 of 10 animals. Administration of 10 mg doses under similar conditions induced neurogenic malignancies in 10, glandular stomach tumors in 4 and adenocarcinoma of the pancreas in 1 of 16 rats. The average latency period was 490 and 400 days resp. for the 2 experimental groups. Single doses of 25, 50, 100, and 200

mg/kg of MNB (p.o. in oil suspension) induced squamous cell carcinoma of the forestomach in 5 and gastric adenocarcinoma in 1 of 15 rats, squamous cell carcinoma of the forestomach in 4 and adenocarcinoma of the pylorus in 1 of 10 rats, malignant tumors of the stomach in 3 and brain tumor in 1 of 8 rats, and forestomach tumors in 5 of 8 rats resp. The 11 rats given 400 mg/kg MNB developed a total of 16 malignant tumors of which neuroinomas or tumors of gastric locations were prevalent. The latency period decreased from 622 to 172 days with the increasing doses. Stomach and nervous system appeared to be the main targets for MNB carcinogenesis confirming the neurotropic effects of the urea group and the preferential tropism towards the glandular stomach.

- 2253 SKIN TUMORS IN MICE PAINTED WITH N-METHYL-N'-NITRO-N-NITROSOGUANIDINE AND N-ETHYL-NITRO-N-NITROSOGUANIDINE. (E.) Takayama, S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), N. Kuwabara, Y. Azama and T. Sugimura. *J Nat Cancer Inst* 46(5):973-980, 1971.

Male strain ICR mice were treated with N-methyl-N'-nitro-N-nitrosoguanidine (MNG) or N-ethyl-N'-nitro-N-nitrosoguanidine (ENG) by topical application between the scapulae according to 1 of 5 protocols: group 1 consisted of 10 mice given a 0.15% solution of MNG for 5 months, group 2 consisted of 10 mice given a 0.3% solution of MNG for 5 months, group 3 consisted of 20 mice given a 0.5 solution of MNG for 5 months, group 4 consisted of 14 mice given a 0.5% solution for ENG for 5 months, and group 5 consisted of 15 mice given acetone solvent only for 5 months (controls). Squamous cell carcinomas developed in 4 of the mice in group 1, in 3 of 18 surviving mice in group 3 and in 5 mice in group 5. Groups 2 and 4 did not develop squamous cell carcinomas. Fibrosarcomas developed in 4 mice in group 1, in 6 mice in group 2, in 7 mice in group 3, in 1 mouse in group 4 and in none of the controls. In some tumor nodules squamous cell carcinoma and fibrosarcoma were found together; the nodules were designated "colliding malignant tumors". Colliding tumors were found in 1 mouse in group 1, in 2 mice in group 2, in 5 mice in group 3, in no mice in group 4 and in none of the controls.

- 2254 QUANTITATIVE ASPECTS OF THE REPAIR OF ALKYLATED DNA IN CULTURED MAMMALIAN CELLS. II. NON-SEMICONSERVATIVE DNA SYNTHESIS ('REPAIR SYNTHESIS') IN HeLa AND CHINESE HAMSTER CELLS FOLLOWING TREATMENT WITH ALKYLATING AGENTS. (E.) Roberts, J. J. (Roy. Cancer Hosp., London, England), J. N. Pascoe, B. A. Smith and A. R. Crathorn. *Chem Bio Interact* 3(1):49-68, 1971.

DNA "repair synthesis" in HeLa and Chinese hamster cells was followed by monitoring loss of labeled methyl and alkyl groups following treatment with various concentrations of N-methyl- and N-ethyl-N-nitro-N-nitrosoguanidine, N-methyl-N-nitrosourea,

thyl and ethyl methanesulphonate or mustard gas. The extent of repair synthesis was directly proportional to the amount of overall DNA alkylation in both cell lines and continued at an approximately equal rate up to 9 hr in hamster cells following alkylation and up to 12 hr in HeLa cells following alkylation with mustard gas. Repair synthesis occurred in both strands of DNA and was not inhibited by the substitution of 5-bromuracil for thymidine in DNA or by hydroxyurea. The ratio of specific activities of DNA synthesized by 'repair' and normal processes under several experimental conditions was similar.

55 CONTROLLING FACTORS IN URETHAN CARCINOGENESIS IN MICE: EFFECT OF ENZYME INDUCERS AND METABOLIC INHIBITORS. (E.) Yamamoto, R. S. Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md., J. H. Weisburger and E. K. Weisburger. *Cancer Res* 31(5):483-486, 1971.

Strain A/J mice were given a single i.p. injection of 1 mg urethan per g body wt following pretreatment with one of 5 microsomal enzyme inducers: chlordane, phenobarbital, β -naphthoflavone, phenothiazine or diethylaminoethyl diphenyl valerate (SKF-525A). Mice given urethan and no pretreatment developed 12 lung tumor nodules/mouse while mice pretreated with chlordane, phenobarbital or β -naphthoflavone developed 12, 10.3 and 13.3 nodules/mouse, resp. Phenothiazine and SKF-525A failed to reduce the number of lung tumor nodules developed. None of the microsomal enzyme inducers were carcinogenic to the lung by themselves. In mice given 3-methylcholanthrene, the incidence of ensuing tumors was reduced by a subsequent dose of urethan. Actinomycin D, puromycin, and cycloheximide failed to affect the incidence of tumors developed by mice treated with these agents and urethan.

56 GASTRIC TUMORS AND LUNG LESIONS IN THE RAT FOLLOWING THE INTRAGASTRIC OR INTRAPERITONEAL ADMINISTRATION OF N-(β -CHLOROETHYL)-N-NITROURETHAN. (E.) Schoental, R. (Med. Res. Council, Carshalton, Surrey, England) and J. P. M. *Cancer Res* 31(5):573-576, 1971.

Twenty-four weanling male rats were given 1 or 2 intragastric doses of N-(β -chloroethyl)-N-nitro-urethan (CENU) in amounts ranging from 2-50 mg/kg body wt. In those rats which were given a dose higher than 10 mg/kg death occurred within 2-14 days. Of 12 rats which survived longer than 1 yr after CENU treatment, 3 developed tumors in the fundular stomach, 1 developed a tumor of the forestomach and 1 developed a tumor of the esophagus. Stomach tumors were usually well-differentiated. Of 19 rats given 5 mg/kg CENU by i.p. injection, 10 survived for more than 6 months, and many died shortly after treatment.

57 ASBESTOS AND MESOTHELIOMAS. (E.) Godwin, M. C. (St. Mary of Nazareth Hosp., Chicago, Ill.) and J. Jagatic. *Environ Res* 3(5-6):391-416, 1970.

The role of asbestos exposure in the development of mesothelioma was investigated in 7 patients. Two female patients who died at 43 and 57 yr-of-age after 24 and 34 yr, resp., from the first exposure to asbestos had abdominal mesothelioma; the duration of exposure was 3 yr in the former and 13 yr in the latter case. Two male patients died of pleural mesothelioma 16 yr after a 16-yr exposure and 25 yr after a 3-yr exposure to asbestos. Two male patients died of abdominal mesothelioma 34 yr after a 13-yr exposure to asbestos. One female died with a pleural mesothelioma 41 yr after a 6-wk exposure to asbestos when she was 14 yr-of-age. Asbestos bodies were always found in the carcinomatous stroma, in the hilar nodes, in the lateral visceral pleural macrophages and lymphatics. Asbestos bodies, fragments, particles and dust seemed to be transported throughout the body and deposited mainly in the nodes, spleen and liver. Apparently carbon, silica and asbestos material were passed through hilar, mediastinal and clavicular nodes entering the circulatory system. Carbon and silica appeared to be localized in the liver and spleen. Asbestos bodies were also found in the intestinal mucosa. The dust found in the abdominal nodes and viscera may have been carried by the lymphatics. Mechanical irritation and chemical effects due to iron-containing compounds such as ferritin or hemosiderin were considered among the main malignancy-inducing factors in asbestosis.

2258 TUMORS IN MICE INDUCED BY AIR PARTICULATE MATTER FROM A PETROCHEMICAL INDUSTRIAL AREA. (E.) Rigdon, R. H. (U. Texas Med. Branch, Galveston) and J. Neal. *Texas Rep Biol Med* 29(1):109-123, 1971.

An air sampler was used to collect air pollutants from the area of a petrochemical plant in Texas City, Texas; air pollutants were collected 24 hr/day, 6 days/wk for 5 yr. A progressive increase in the amount of particulate matter in the air samples was seen during the period of collection. The concentrations of benzene-solubles and benzo(a)pyrene also increased in the air samples. Benzene-solubles and benzo(a)pyrene were extracted from the air samples and injected s.c. into strain CFW mice in amounts ranging from 1-20 mg. Benzene-solubles produced local fibrosarcomas in 40-61% of mice injected with 2.5-10.0 mg. Benzo(a)pyrene (0.025-2.0 mg) extracted from the air samples and injected into mice caused fibrosarcomas in 33-90% of mice. No tumors occurred in mice treated with benzene-solubles collected at areas other than the Texas City plant. Commercially-produced benzo(a)pyrene produced fewer tumors in treated mice than did the benzo(a)pyrene extracted from the air pollution samples, which may have been due to the presence of cocarcinogens in the air samples.

2259 THE PRESENCE OF RESINS AND 3,4-BENZOPYRENE IN THE ATMOSPHERE OF THE ELECTROLYSIS SHOPS IN ALUMINIUM PLANTS: THEIR ROLE IN CARCINOGENESIS. (Rus.) Konstantinov, V. G. (Sverdlovsk Med. Inst., U.S.S.R.) and A. I. Kuzminyuk. *Gig Sanit* 3:39-42, 1971.

Resinous compounds in the occupational environment of electrolysis operations within aluminium plants of Irkutsk varied from 8 to 2,400 mg/m³ and the levels of benzo(a)pyrene varied from 1 to 1,800 µg/m³ depending on the sampling area. Mortality from malignant neoplasia among male workers engaged in shops with self-burning anodes was 1.9 times higher for the whole group, 7.2 times higher among the 18-39-yr-old group and 1.6 times higher among above 40-yr-old workers than the urban area population over an 11 yr period (1956-1966). Mortality from lung, bronchial or pleural cancer was 1.7 times higher among the same workers (whole group), 8.3 times higher among the young and 1.6 times higher among the middle-aged group than among the urban population of the area. No significant excess in mortality from malignancy was observed among workers engaged in shops with burnt anodes who had no contact with coal pitch.

- 2260 A STUDY OF TOBACCO CARCINOGENESIS: XI. TUMOR INITIATORS, TUMOR ACCELERATORS, AND TUMOR PROMOTING ACTIVITY OF CONDENSATE FRACTIONS. (E.) Hoffmann, D. (Amer. Hlth. Found., New York, N. Y.) and E. L. Wynder. *Cancer* 27(4):848-864, 1971.

The BI subfraction of cigarette smoke condensate, a portion which contains polynuclear aromatic hydrocarbons, N- and O-heteroaromatic compounds, chlorinated insecticides and some of their pyrolysis products, esters, terpenes and quinones, was separated into 5 parts. One of these parts, BIh, comprised 0.09% of total cigarette "tar" and 15% of the subfraction BI; BIh contained 48% of the benzo(a)pyrene content of subfraction BI. The BIh portion was chromatographed into 80 subfractions and each subfraction was tested for tumorigenicity by administering it topically to strain Ha/ICR mice. BIh subfractions 56-66 were highly tumorigenic; the tumor incidence among mice given these fractions ranged from 17% to more than 80%. Fractions 70-80 were also effective as tumor initiators and produced tumor incidences of 35-65%. While fractions 56-66 contained no known carcinogens, other fractions of BIh contained alkylated fluoranthenes, cyclophenanthrenes and chrysene. It was noted that only the acidic portions of tobacco "tar" fractions showed appreciable tumor-promoting efficacy.

- 2261 INFLUENCE OF CIGARETTE SMOKE ON GUINEA PIGS: EFFECT ON PULMONARY CELLS AND SERUM ANTITRYPSIN LEVELS. (E.) Flint, G. L. (VA Hosp., Salt Lake City, Utah), K. W. Maxwell and A. D. Renzetti, Jr. *Arch Environ Health* 22(3):366-369, 1971.

Male guinea pigs were exposed to the smoke of 40 cigarettes/day for 2 wk and to the smoke of 20 cigarettes/day for 8 wk thereafter, and the number and type of cells recoverable from the lungs were noted together with the antitrypsin contents of serum. More total cells were recoverable from the lungs of animals exposed to smoke than from animals not exposed to smoke; the overall mean number of cells recovered from the lungs of treated guinea

pigs was 11.7×10^6 and the overall mean number of cells recovered from the lungs of controls was 8.1×10^6 . Fifty percent of cells recovered from the lungs of exposed animals were polymorphonuclear leukocytes while 24% of cells recovered from control lungs were polymorphonuclear leukocytes. No changes were seen in the levels of serum antitrypsin levels during the 10 wk experimental period in exposed animals.

- 2262 TEMPORAL CHANGES IN DNA AND RNA SYNTHESIS IN THE REGENERATING LIVER OF HYDROCORTISONE-TREATED RATS. (E.) Rizzo, A. J. (McGill U. Cancer Res. Unit, Montreal, Quebec, Canada), P. Heilpern and T. E. Webb. *Cancer Res* 31(6):876-881, 1971.

Male rats were partially hepatectomized 19 hr prior to administration of 50 mg/kg hydrocortisone. It was found that hydrocortisone inhibited a rise in DNA synthesis in the regenerating liver. In non-hepatectomized rats not given hydrocortisone, DNA synthesis (measured by the uptake of ³H-thymidine by liver cells in cpm/µg deoxyadenosine) rose from 5-21 cpm/µg during 20-26 hr after hepatectomy; however, in hydrocortisone-treated rats, there was no appreciable increase in DNA synthesis 20-32 hr after hepatectomy. Between 32 and 36 hr, as DNA synthesis in untreated hepatectomized rats declined, DNA synthesis in hydrocortisone-treated animals increased from 5-42 cpm/µg. Further, the rate of ribosome formation in hydrocortisone-treated rats increased by 150-200% over controls by 26 hr postoperative; by 32 hr postoperative, the increase in ribosome formation in hydrocortisone-treated rats was 120-200% over controls. Most of the increase in ribosome formation in treated rats was thought to be due to increased transport of ribosomal subunits to the cytoplasm.

- 2263 CARCINOGENICITY OF INDUSTRIAL CHEMICALS: PROPYLENE IMINE AND PROPANE SULFONE. Ulland, B. (Bionetics Res. Labs., Inc., Kensington, Md.), M. Finkelstein, E. K. Weisburger, J. M. R. and J. H. Weisburger. *Nature* 230(5294):460-461, 1971.

Groups of 26 rats were given p.o. doses of either 10 mg/kg propylene imine for 28 wk or 56 or 28 mg/kg propane sulfone for 32 wk. Of the 52 rats given 20 mg/kg propylene imine 28 developed tumors and of the 52 rats given 10 mg/kg propylene imine 45 developed tumors. Tumors in the propylene imine group included 30 breast tumors among females, 1 gliomas, 9 ear duct tumors, 10 leukemias, 4 intestinal tumors and 10 "miscellaneous" tumors. Propane sulfone at both dose levels gave rise chiefly to gliomas (56 gliomas developing in the 52 rats treated). Breast tumors, ear duct tumors, leukemias, intestinal tumors and miscellaneous tumors also developed in rats given propane sulfone, and intestinal tumors were more common in the propane sulfone group than in the propylene imine group.

- 4 A STUDY OF PRECURSOR ILLNESS IN LUNG CANCER PATIENTS. (E.) Stavrakys, K. M. (Community Med., U. Western Ontario, Canada). *Chronic Dis* 23(10-11):691-705, 1971.
- The histories of 526 Canadian veterans who had died of lung cancer were matched for age, occupation, residence and cigarette smoking habits with an equal number of controls without lung cancer. Illness patterns emerging prior to the onset of cancer were compared. No significant pattern, however, emerged in the cancer group which would have permitted the prediction of susceptibility to lung cancer. Minor differences in illness patterns were found between cancer cases and non-cancer cases that appeared to be related to smoking habits. It was found that cancer patients smoked more intensely than non-cancer patients who smoked the same number of cigarettes (smoking "intensity" was measured by measuring amount of smoking and duration of each cigarette).

- 2274 PROTEASE ACTIVITY CHANGES IN RABBIT LUNG
MACROPHAGES, SPLEEN CELLS AND POLYMOR-
PHONUCLEAR LEUCOCYTES AFTER WHOLE-BODY X-IRRADIATION.
(E.) Kotulova, D. (Fac. Med., Comenius U., Bratis-
lava, Czechoslovakia) and J. Stefanovic. *Folia*
Biol (Praha) 17(1):26-32, 1971.

Intracellular protease activity (at pH 3.2 and pH 2) in polymorphonuclear leukocytes, spleen cell sus-
pensions (70% lymphocytes) and alveolar macrophages
was investigated in 84 rabbits 1 hr and 1, 2, 3, 6,
10 and 20 days after exposure to whole-body irradi-
ation (500 R). The proteolytic activity of poly-
morphonuclear leukocytes increased during the 1st
few hr, decreased on the 6th day and returned to
normal values by the 10th day following exposure;
no further changes in activity were recorded at pH
2 but a significant increase in activity was
observed at pH 3.5 20 days after exposure. Lung
macrophages elicited a 95% increase in protease
activity the 6th through the 10th day; protease
returned to normal values on the 20th day of the
experiment at both pH levels. The proteolytic
activity of spleen cell extracts determined at pH
3.5 displayed a biphasic course: an 80% increase
occurred on the 1st day and a second peak was
recorded on the 10th day with a decrease to almost
normal values on the 20th day following irradiation.
The increased proteolytic activities seemed to be
due to enzyme participation in the lysis of protein
from injured cells.

- 2275 BONE MARROW, SPLEEN, AND THYMUS REGENERA-
TION PATTERNS IN MICE AFTER WHOLE-BODY
IRRADIATION. (E.) Takada, A. (Roswell Park Mem.
Inst., Springville, N. Y.), Y. Takada, U. Kim and
J. L. Ambrus. *Radiat Res* 45(3):522-535, 1971.

Male mice of the CBA/St strain were exposed to 400 r
of whole-body X-irradiation; some mice had been
thymectomized prior to irradiation. Spleen weight
in irradiated mice decreased from 77 mg at irradiation
to a low of 30 mg on day 5 postirradiation, there-
after recovering rapidly to attain a maximum of 180
mg on day 18. Injection of 5×10^6 bone marrow cells
following irradiation induced an earlier recovery of
spleen weight after irradiation, and shielding the
right femur during irradiation had a similar effect.
Following irradiation, the thymus showed a biphasic
pattern of weight change. Incorporation of ^{59}Fe by
spleen and bone marrow declined following irradiation
until day 2 and then increased until days 6-7
after which label incorporation declined again
before making a rapid recovery between days 11 and
18 postirradiation. Incorporation of $^{125}\text{IUdR}$ in
spleen, bone marrow and thymus showed a similar pat-
tern of decline and recovery following irradiation.
Injection of bone marrow cells following irradiation
produced an earlier recovery of ^{59}Fe and $^{125}\text{IUdR}$
incorporation; in animals given bone marrow cells,
incorporation peaked on day 10 postirradiation.
Shielding of the femur during irradiation similarly
produced more rapid recover of ^{59}Fe and $^{125}\text{IUdR}$
incorporation; however, cells migrating from bone
marrow to spleen in the protected mice commenced
synthesis of hemoglobin immediately while injected

bone marrow cells did not initiate division or hem-
oglobin synthesis for as long as 2 days after
irradiation.

- 2276 A QUANTITATIVE ANALYSIS OF BONE MARROW
CELL POPULATIONS IN IRRADIATED AND NON-
IRRADIATED MICE TREATED WITH 19S ALPHA-2 GLOBULIN
($\alpha_2\text{-MG}$). (E.) Sontag, J. M. (Weizmann Inst. Sci.
Rehovot, Israel), N. Trainin and I. Berenblum.
Radiat Res 45(3):499-510, 1971.

Mice of strain C57BL/6 were treated with 4 i.v.
injections of 0.50 mg of 19S α_2 -globulin prior to
exposure to 680 r of X-irradiation. Cell volume
distribution was measured in bone marrow of treated
mice with a device similar to a Coulter counter.
The volume distribution of cells from normal
unirradiated mice fell into 3 categories: cells
with volumes of $10\text{-}107 \mu^3$ (group 1), cells with
volumes of $108\text{-}214 \mu^3$ (group 2), and cells with
volumes of $215\text{-}425 \mu^3$ (group 3). In unirradiated
mice treated with α_2 -globulin, the number of group
1 cells rose after 6 hr of treatment from 10×10^6
to 13×10^6 , thereafter falling to 5×10^6 on day
posttreatment. At the same time, cells in group
dropped from 8×10^6 after 1 hr of treatment, to
 $\times 10^6$ by 12 hr and recovered by day 5. In mice
treated with α_2 -globulin and given irradiation,
(and in untreated irradiated mice), cells in group
1 rose from about 10×10^6 at 1 hr after treatment
to about $19\text{-}21 \times 10^6$ at 24 hr after treatment,
falling to initial values by day 8. Groups 2 and
declined markedly following irradiation. Treatme-
with α_2 -globulin stimulated recovery of group 3.

- 2277 FACTORS REGULATING THE PROLIFERATION AND
MIGRATION OF HEMATOPOIETIC STEM CELLS.
(E.) Fried, W. (Sec. Hematology, Div. Med., Rush
Presbyterian St. Luke's Med. Ctr., Chicago, Ill.)
J Lab Clin Med 77(2):239-246, 1971.

Female mice of the CF₁ strain were exposed to X-ir-
radiation at a dose rate of 30-50 rads/min with 1
leg shielded from X-rays; numbers of hematopoietic
stem cells (HSC) in the organs of the animals were
determined by observing the number of colony form-
ing units in selected tissues. In all tissues
studied, the number of colony forming units was
greater in irradiated mice than in unirradiated
mice; a dose of 300 rads produced 20 colony form-
ing units in spleens of irradiated mice, while unirra-
diated mice spleens showed less than 1 unit. Colon-
forming units were not significantly more abundant
in the shielded legs of irradiated mice than in 1
of unirradiated mice. Irradiated mice were expos-
ed to an additional 200 rads and previously unexposed
control mice also received 200 rads X-rays; the num-
ber of colony forming units in the bone marrow of
both irradiated mice and control mice declined to
10% of normal. However, by 24 hr after the 200 r
dose, the number of colony forming units in the
marrow of mice given the priming irradiation was
twice as much as that of mice not exposed to prim-
ing irradiation. The percentage of colony forming un-

surviving vinblastine treatment in the shielded marrow and in marrow of unirradiated mice was not significantly different; however, the percentage of colony forming units surviving vinblastine treatment in the unshielded marrow was less than half that surviving in the marrow of unirradiated mice or in the shielded marrow of irradiated mice.

2278 A CYTOLOGICAL STUDY OF BONE MARROW AND PERIPHERAL BLOOD OF IRRADIATED AND NON-IRRADIATED MICE TREATED WITH 19S ALPHA-2 GLOBULIN (α_2 -MG). (E.) Sontag, J. M. (Weizmann Inst. Sci., Rehovot, Israel), I. Berenblum and N. Trainin. *Radiat Res* 45(3):511-521, 1971.

Female strain C57BL/6 mice were exposed 4 times to 170 r of X-irradiation and treated subsequently with an i.v. injection of 0.50 mg 19S α_2 -globulin; the effects of treatment on populations of cells in bone marrow and peripheral blood were observed. In irradiated and unirradiated mice given α_2 -globulin, granulocytosis followed treatment; in these groups, granuloid cells increased in bone marrow until 3 days after treatment, thereafter dropping to sub-normal levels before returning to normal levels on day 10. Lymphocytes and lymphocyte-like cells in bone marrow of mice given α_2 -globulin but no irradiation increased following treatment; enhanced production of granulocytes followed lymphocyte increase in these experimental groups. Lymphocyte and granuloid cells in bone marrow of irradiated mice given α_2 -globulin recovered normal levels more quickly than did cells of mice not given α_2 -globulin. In the peripheral blood, leukocyte counts of mice given irradiation fell following irradiation, and recovered only gradually; by 21 days after irradiation, counts of leukocytes in this group were $1.5 \times 10^3/\text{mm}^3$. In irradiated mice given α_2 -globulin, however, leukocyte counts recovered more quickly; at 21 days after irradiation leukocyte counts in this group reached $4 \times 10^3/\text{mm}^3$.

2279 AUTORADIOGRAPHIC STUDIES ON ^3H -THYMIDINE INCORPORATION IN THE LIVER AND KIDNEYS OF IRRADIATED MICE. (E.) Unger, E. ("Frederic Joliot-Curie" Natl. Res. Inst. Radiobiol. Radiohygiene, Budapest, Hungary) and J. Gidali. *Strahlentherapie* 41(3):354-357, 1971.

Mice were exposed to 200, 450 or 700 r of X-irradiation and the incorporation of ^3H -thymidine into liver and renal tubulus cells of irradiated mice was observed at various times after irradiation. Tritiated thymidine uptake, expressed as a percentage of uptake in unirradiated mice, decreased in liver and kidney cells until 6 days postirradiation. No clear correlation was seen between increased dose of irradiation and increased or decreased thymidine labeling index. In liver cells given 450 r, the percentage of labeled cells dropped from 37% of control values immediately after irradiation to 10% by 24 hr postirradiation; at 72 hr postirradiation, the labeling index was still 10% of control. However, by 6 days postirradiation, the labeling index amounted

to 17% of control values; at 9 days postirradiation, the percentage of cells incorporating ^3H -thymidine was 60% of control values. Liver and kidney cells of irradiated mice never returned to normal.

2280 CHROMOSOMAL ABNORMALITIES IN LYMPHOCYTES OF CHILDREN AND BABY RABBITS BORN FROM MOTHERS TREATED BY X-IRRADIATION BEFORE PREGNANCY: A TRANSPLACENTARY PLASMATIC CHROMOSOME-DAMAGED FACTOR? (E.) Goyanes-Villaescusa, V. (Med. Santiago de Compostela, Spain). *Blut* 22(2):93-96, 1971.

Karyotype studies were performed on the offspring of 6 women given non-pelvic radiotherapy in amounts ranging from 4,000-12,000 r, 2-8 months prior to pregnancy and in the offspring of 3 rabbits given whole-body X-irradiation (120 r/day) a week before breeding. All children showed a high frequency of unstable chromosome aberrations (e.g., 13.50% incidence) compared to the 4 children of unirradiated mothers who showed a 2.5% incidence of unstable chromosomal aberrations. The frequency of gaps, breaks, and dicentric in the children of irradiated mothers was 10, 2.65, and 0.65%, resp., while the frequency of these 3 aberrations in the children of unirradiated mothers was 1.9, 0.6, and 0%, resp. The frequency of unstable aberrations in the irradiated female rabbits and in unirradiated rabbits was 20 and 3%, resp. It was thought that a lymphocyte chromosome-breaking factor was induced in women and in female rabbits by irradiation, and that this factor passed through the placenta producing aberrations in offspring.

2281 INCIDENCE OF DOMINANT LETHAL MUTATIONS AFTER X-IRRADIATION OF SPERMATOZOA OF MICE AND RATS. (E.) Gilliavod, N. (Nuclear Energy Study Ctr., Mol, Belgium) and A. Leonard. *Strahlentherapie* 41(3):351-353, 1971.

Male BALB/c mice and male rats were exposed to 400 r of whole-body X-irradiation and mated for a period of 7 days with 3 virgin females immediately thereafter. On day 17, after the initiation of the mating period, females were killed and dissected and the numbers of corpora lutea and living and dead embryos were noted. The incidence of dominant lethality induced in spermatozoa by the irradiation was found to be approximately 50% higher in rats than in mice.

2282 CELL POPULATION KINETICS IN ACUTE INTESTINAL RADIATION DEATH. (E.) Okumura, Y. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan) and T. Matsuzawa. *Strahlentherapie* 41(3):358-362, 1971.

The cell renewal system in which cells produced in the crypts of the small intestine migrate to the villi was used as a model for the study of cell population kinetics in acute radiation death; the crypt cells were designated the "proliferative" compartment in the model and the villi cells the

"functional" compartment. Radiation death was induced in CFW mice by 300 r of X-irradiation. After irradiation, the cell number in the proliferative compartment decreased exponentially. Change in the cell number in the functional compartment was expressed in terms of the numbers of influx and efflux cells, and the decline in the cell number in the proliferative compartment produced a subsequent depletion in the functional compartment. The cell renewal system model was thought to give an adequate picture of the mechanism of cell denudation following radiation.

2283 CHROMOSOME DAMAGE IN THYROID CELLS OF ADULTS IRRADIATED WITH X-RAYS IN INFANCY.

(E.) Doida, Y. (U. Rochester Sch. Med. Dent., N. Y.), C. Hoke and L. H. Hempelmann. *Radiat Res* 45(3):645-656, 1971.

Cells from neoplastic and nonneoplastic thyroids of 4 humans given (in 2 cases) 728 and 468 r of X-irradiation in infancy together with 50 μC ^{131}I were examined for chromosomal aberrations. These patients were aged from 28-37-yr-old. Controls consisted of patients given ^{131}I but no irradiation and subjects given neither ^{131}I nor irradiation. Aneuploid metaphases were more common in thyroid cells from the X-irradiated group than in controls; the percentages of aneuploid metaphases in irradiated patients ranged from 6.4-20.8%, while percentages of aneuploid metaphases from unirradiated ^{131}I -treated patients ranged from 0-17.8%, and percentages of aneuploid metaphases from patients given neither X-irradiation nor ^{131}I ranged from 0-3.8% (0% in 5 of 7 patients in this group). Aneuploid metaphases were in all groups more common in normal cells than in neoplastic cells. In both neoplastic and normal cells the frequency of unstable aberrations was 3.5% in irradiated patients; this frequency was 10 times higher than the frequencies of unstable aberrations in either of the control groups. The frequency of stable aberrations in X-irradiated patients was 32.6% in normal thyroid cells and 22.6% in neoplastic cells. In controls, the frequency of stable aberrations in normal and neoplastic cells never exceeded 2%.

2284 EFFECT OF INTERNAL EXPOSURE BY ^{90}Sr AND ^{131}I ON RESPIRATORY $^{14}\text{CO}_2$ PATTERNS FOLLOWING ^{14}C -GLUCOSE ADMINISTRATION IN MICE. (E.) Matsuoka, O. (Natl. Inst. Radiol. Sci., Chiba, Japan), E. Muramatsu and M. Kashima. *J Radiat Res* 11(3-4):157-165, 1970.

Male hybrid mice of strain CF1 and RF were given 2 $\mu\text{C/g}$ body weight of ^{90}Sr or 5 $\mu\text{C/capita}$ ^{131}I , and the effects of this irradiation on the respiratory $^{14}\text{CO}_2$ patterns were compared using ^{14}C -glucose. Parameters compared in ^{90}Sr - and ^{131}I -irradiated mice included the time elapsing between irradiation to maximum specific exhalation of $^{14}\text{CO}_2$ and CO_2 (peak time) and the maximum exhalation activity at the peak time. In unirradiated mice, the value for specific activity of exhaled $^{14}\text{CO}_2$ had a maximum height of

1525 cpm/ CO_2 mM and a peak time of 26.1 min. In mice given ^{90}Sr irradiation, the maximum height did not differ significantly from that seen in unirradiated mice, but the peak time was decreased to 17.5-20 min. In mice given ^{131}I , the peak time for specific activity of exhaled $^{14}\text{CO}_2$ was not significantly different from that seen in unirradiated mice, but the maximum value for specific $^{14}\text{CO}_2$ exhalation activity was increased to 2039-2051 cpm/ CO_2 mM. L-thyroxine and insulin produced a stimulatory effect; maximum height of specific $^{14}\text{CO}_2$ activity was increased and peak time was decreased in irradiated mice given these agents. 5-Hydroxytryptamine and carbon tetrachloride inhibited the specific activity of $^{14}\text{CO}_2$ in irradiated mice.

2285 PATHOLOGIC EFFECTS OF DIFFERENT DOSES OF RADIOSTRONTIUM IN MICE: DEVELOPMENT AND INCIDENCE OF LEUKAEMIA. (E.) Nilsson, A. (Res. Inst. of Natl. Defense, Sundbyberg, Sweden). *Acta Radiol* 10(1):115-128, 1971.

The incidence of leukemia and related conditions observed among 1,430 strain CBA mice which were injected i.p. with doses of $^{90}\text{Sr}(\text{NO}_3)_2$ ranging from 0.2-1.6 $\mu\text{C/g}$ body wt. Mice were killed 7, 14, 30 days after treatment with ^{90}Sr and their blood and selected organs were examined for leukemia. In the treated rats, 991 died before being killed for examination. A total of 98 cases of leukemia were discovered in the ^{90}Sr -irradiated mice. The highest incidence of leukemia developed among mice given 1.6 $\mu\text{C/g}$ ^{90}Sr (28.0% incidence) and the lowest incidence developed among mice given 0.2 $\mu\text{C/g}$ ^{90}Sr (1.7% incidence). Of the 98 cases of leukemia developed by the irradiated mice, 97 were thought to have arisen from the lymphatic cells; there were 60 cases of marrow lymphomas and 21 thymic lymphomas. There were 16 cases of "generalized lymphoma" and 1 case each of myeloid and chronic lymphocytic leukemia.

2286 DETECTION OF A LUNG TUMOR AGENT IN BALB/c/Cb/Se IRRADIATED MICE. (E.) Squartini, F. (Inst. Pathological Anat. and Histology, U. Pisa, Italy) and G. B. Bolis. *Lav Ann Anat* Perugia 30(3):125-128, 1970.

Castrated male and intact female mice of BALB/c/Se strain, the offspring of sibling mates, were exposed to 500 r whole-body X-irradiation; 30 days thereafter, the mice were implanted with the parenchyma of newborn donors. Of 29 irradiated plant recipients, 8 developed thymic leukemia; none of the 30 unirradiated recipients developed leukemia. Five of the irradiated recipients developed alveolar adenomas in the lung grafts; no adenomas developed in the lung grafts of nonirradiated mice.

2287 QUANTITATIVE CHANGES OF ACID PHOSPHATASE IN THE HYPOTHALAMUS, PITUITARY, ADIPOSE TISSUE AND THYROID OF MICE (*Mus musculus* L.) EXPOSED TO

ARGE, SINGLE DOSES OF UV OR X-RAYS, TAKING INTO ACCOUNT THE CIRCADIAN RHYTHM. (E.) Surowiak, J. Dept. Anim. Physiol., Jagiellonian U., Cracow, Poland). *Folia Biol* 17(2):105-140, 1969.

Male and female mice were subjected to either a single dose of 1800 r of X-irradiation at 11 a.m. or a single dose of UV irradiation (254-405 nm) between 10 and 11 a.m. and the effect of these treatments on the circadian rhythm of acid phosphatase in various organs was noted. In the hypothalamus of unirradiated male animals the maximum acid phosphatase activity was seen at 6 p.m. and the minimum at midnight; in males given X-irradiation, the minimum acid phosphatase activity was seen at noon and at 6 p.m. UV produced a circadian pattern of acid phosphatase in the hypothalamus similar to that seen in unirradiated animals. In females given X-irradiation, the maximum levels of acid phosphatase in the hypothalamus were seen at 6 p.m. and midnight and the minimum values were seen at noon and 6 a.m. UV irradiation of females did not alter the normal acid phosphatase pattern until 12 hr after treatment; thereafter enzyme levels declined until 24 hr after treatment. Other organs and glands tested included the hypophysis, adrenal and thyroid. In all test targets, X-rays caused changes in acid phosphatase activity during the first 12-18 hr after treatment; enzyme levels usually returned to normal by 24 hr after treatment. In the other organs, as in the hypothalamus, UV and X-irradiation increased acid phosphatase in males and decreased acid phosphatase in females.

88 SUNLIGHT EXPOSURE AND RISK OF DEVELOPING CUTANEOUS AND ORAL SQUAMOUS CELL CARCINOMAS IN WHITE CATS. (E.) Dorn, C. R. (Sch. Vet. Med., U. Missouri, Columbia), D. O. N. Taylor and R. Schneider. *Nat Cancer Inst* 46(5):1073-1078, 1971.

The incidence of squamous cell carcinoma among domestic cats in Alameda County, California in 1965 was investigated. It was found that the annual incidence rates for carcinoma in this area were 26.9 cutaneous cases/100,000 cats and 9.0 oral cases/100,000 cats, suggesting that skin protected from exposure to sunlight is less apt to develop squamous carcinoma than skin which is regularly exposed to sunlight. Male and female cats, and spayed and intact cats did not show differing risks of developing squamous cell carcinoma. White cats had a risk of developing cutaneous squamous cell carcinoma 13 times greater than cats of other colors, but a similar difference in risk for white and non-white cats was not found for oral carcinoma. A low rate of incidence of cutaneous carcinoma was found for Siamese cats, the result perhaps of their non-white hair coat. Eighty-seven of the 149 squamous cell carcinoma cases in cats involved the ears and nose, areas which have comparatively little hair.

89 HOST RESISTANCE AND RADIATION RESPONSE OF SYNGENEIC MOUSE LYMPHOMA CELLS. (E.) Suyama, Y. (Coll. Med. Sci., U. Minnesota, Minneapolis). *J Nat Cancer Inst* 46(5):963-971, 1971.

Strain C57BL mice were exposed to 400 r of whole-body X-irradiation several hours to 1 day prior to challenge with cells from an LSA ascites lymphoma. Tumor takes in irradiated and unirradiated animals were compared. Most tumor takes represented the outgrowth of a single cell. In unirradiated mice, tumor takes following challenge ranged from 5/20 to 17/20, while in irradiated animals tumor takes ranged from 12/26 to 10/20. In a related experiment, irradiated and unirradiated mice were challenged with lymphoma cells killed by *in vitro* irradiation with 6000-9000 r. Prolongation of median survival time and a dose-dependent decrease in tumor takes were seen in unirradiated mice given X-ray killed lymphoma cells. Addition of numbers of killed cells to viable cells in the tumor cell challenge did not affect the incidence of tumor takes.

2290 THE EFFECTS OF X-RAYS ON THE SYNTHESIS OF DNA, RNA, AND PROTEINS IN SYNCHRONIZED CHINESE HAMSTER CELLS. (E.) Bacchetti, S. (Argonne Natl. Lab., Ill.) and W. K. Sinclair. *Radiat Res* 45(3):598-612, 1971.

Synchronized cultures of Chinese hamster cells were exposed to X-irradiation with a single absorbed dose of 710 rads, and the effect of the irradiation on RNA, DNA and protein synthesis in the cells was observed. Cells irradiated in the G₁ phase were slightly stimulated to enter the S phase but DNA synthesis was normal. Irradiation of cells in the S phase caused an initial decrease in DNA synthesis followed by an increase; in S phase cells the period of DNA synthesis was prolonged. RNA synthesis in irradiated cells increased as cells entered S phase and was maximal during the period of DNA replication; RNA synthesis decreased during G₂. Protein synthesis was stimulated to a greater degree by X-irradiation than either RNA or DNA synthesis. When cells were treated with 50 µg/ml cycloheximide for 3 hr after irradiation in the G₁ and G₂ phases, loss of colony-forming ability and inhibition of nucleic acid and protein synthesis associated with irradiation were somewhat mitigated.

2291 TOXICITY OF TRITIATED THYMIDINE IN P388F LYMPHOMA CELLS: II. EFFECTS ON DNA MOLECULAR WEIGHT. (E.) Peterson, A. R. (Christie Hosp., Manchester, England) and B. W. Fox. *Int J Radiat Biol* 19(3):237-246, 1971.

Mouse lymphoma cells of line P388F were labeled with 10 µCi/ml of tritiated thymidine (³H-TdR) for 30 min at 37°C and the effects of the incorporated tritium label on the molecular weight of DNA synthesized by the lymphoma cells were observed. It was found that the average molecular weight of DNA in the lymphoma cells was inversely related to the level of specific activity of label uptake by cells and to cell survival. At low levels of tritium incorporation, the medium-sized DNA component with an average molecular weight of about 2.5 x 10⁸ daltons was converted into the high molecular weight DNA fraction having an average molecular weight of about 10⁹ daltons. Supralethal

levels of tritium uptake or incubation of the labeled cells at 4°C reduced the average molecular weight of the larger DNA fraction. The decline in the molecular weight of DNA appeared to be produced by excess tritium incorporation due to strand breakage induced by the label.

2292 EFFECTS OF COBALT-60 GAMMA RAYS ON
LYSOZYME IN AQUEOUS SOLUTION. (E.)

Yamamoto, K. (Fac. Sci., Osaka U., Japan). *J Radiat Res (Tokyo)* 11(2):85-91, 1970.

Egg-white lysozyme was exposed to γ -irradiation produced by ^{60}Co in doses ranging from 5.4×10^4 to 1.4×10^6 r. The smaller dose left 95% of lysozyme activity intact, whereas the larger dose left 31% of lysozyme activity intact. In the lysozyme preparation given the smaller dose of γ -irradiation, no significant change is observed in amino acid composition or in amide-nitrogen content. No N-terminal amino acids other than lysine were detected. Polymerized lysozyme was found in irradiated lysozymes in addition to intact lysozyme.

2293 EFFECTS OF X-IRRADIATION ON ^{14}C -PYRUVATE
METABOLISM IN RAT THYMOCYTES. (E.) Araki,
K. (Tokyo Women's Med. Coll., Japan), S. Taguchi, H.
Ohya and T. Yamada. *J Radiat Res (Tokyo)* 11(2):
79-84, 1970.

The effect of X-irradiation on the label distribution of citric acid cycle intermediates from U- ^{14}C -pyruvate was studied in rat thymocyte cells. The glycogen content of irradiated thymocytes was considerably lower than control levels after a 2 hr incubation; malate accumulation was 10-50% above control levels and was dose-dependent (1-8 kR). Chromatographic patterns of citric acid cycle intermediates labeled with ^{14}C -pyruvate were essentially the same between the unirradiated control and irradiated cells. Label incorporation into glucose was decreased by 8 kR irradiation to 28% of control values. These findings indicate that the previously reported increased labeling of citric acid cycle intermediates derived from ^{14}C -glucose after irradiation was due to enhanced substrate flow through glycolysis rather than to stimulation of the citric acid cycle.

2294 THE ROLE OF CHEMICAL CARCINOGENS AND
IONIZING RADIATION IN THE DEVELOPMENT OF
COLONIC ADENOCARCINOMA. (Rus.) Zapol'skaya, N. A. (no affil),
Fedorova, L. N. Lavrent'yev and N. M. Borovikova. *Gig Sanit* 36(1):55-59, 1971.

VIRAL CARCINOGENESIS

STUDIES ON THE RELATIONSHIP OF LEUKEMIA IN ANIMALS AND MAN. (E.) Maruyama, K. (U. as M.D. Anderson Hosp. Tumor Inst., Houston) and Omochowski. *Texas Rep Biol Med* 29(1):83-96, 1971.

Leukemias and sarcomas from animals and men were studied using immunological and ultrastructural techniques, and etiological and antigenic similarities were noted. Material included cultured cells of leukemia and/or sarcoma virus-infected BALB/c mice, cells of bone tumors of hamsters and rats, cells of feline, canine and equine lymphomas, and cells of human patients with various neoplasms. All tumors from animals with spontaneous or virus-induced tumors gave positive mixed hemadsorption reactions with immune sera against murine, feline Rauscher leukemia virus grown in human cells. Electron microscopy revealed C-type virus particles in cell cultures from all species examined, including cells from canine and equine lymphoma. C-type particles replicated in human cells infected with herpesvirus which had been derived from neoplastic cells by inoculation of feline or murine leukemia cells into a Burkitt's lymphoma culture. Herpesvirus particles disappeared in the human cells following replication of C-type virus particles in these cells. In cells from equine lymphoma and from patients with conditions such as thyroid carcinoma, a simultaneous infection of herpesvirus and C-type particles was seen.

DNA DENSITY OF ONCOGENIC AND NON-ONCOGENIC SIMIAN ADENOVIRUSES. (E.) Goodheart, C. (U. Microbiol., U. Illinois Med. Ctr., Chicago). *Virology* 44(3):645-648, 1971.

The density of the DNA from each of 16 simian adenoviruses was determined using CsCl density gradient centrifugation. The molar ratios of guanine and cytosine were also calculated. Densities were determined from the position of each of the viral DNA's on the density gradient relative to the position of bacterial markers *Clostridium perfringens*, *Escherichia coli* and *Micrococcus lysodeikticus*. The densities of these 3 markers were, resp., 1.691 g/ml, 1.710 g/ml, and 1.731 g/ml. The densities of the viral DNA's ranged from 1.709-1.721 g/ml, with a mean density of 1.7148 g/ml. The mean guanine-cytosine molar ratio for the viral DNA's was 55.76%. Considering the oncogenic and non-oncogenic viruses separately, the mean molar ratios of guanine and cytosine were 56.92% and 54.26%, resp. This difference was found to be statistically significant.

TRANSFORMATION OF MURINE CELLS BY TWO "SLOW VIRUSES," VISNA VIRUS AND PROGRESSIVE PNEUMONIA VIRUS. (E.) Takemoto, K. K. (Lab. Viral Dis., Natl. Inst. Allergy and Infect. Dis., Natl. Inst. Hlth., Bethesda, Md.) and L. B. Stone. *J Virol* 7(6):770-775, 1971.

Visna virus and progressive pneumonia virus (PPV) were prepared in sheep testis cell cultures and used to infect mouse cells in multiplicities of 10 plaque

forming U/cell. Three wk later, morphologically altered spindle-shaped cells began to appear in the cultures infected with the 2 viruses. Transformed cells were confined to separate foci within each culture, and there were 40-60 such foci per culture dish. Lines of transformed cells were established from the original infected cultures. On continued passage, the cells from the infected lines lost their initial fibroblastic appearance and became more epithelioid. Supernatants from transformed cultures did not transform other cells in culture. However, when transformed cells were cocultivated with sheep testis cells, the cells yielded virus by 3-4 wk after the beginning of cultivation; rescued virus was identified as visna or PPV. Neither RNA nor DNA tumor viruses, nor the antigens associated with these viruses, could be found in visna virus- or PPV-transformed cells. Transformed mouse cells produced small regressing tumors in untreated mice and large tumors in X-irradiated mice.

2298 TRANSFORMATION AND PRODUCTIVE INFECTION OF HUMAN OSTEOSARCOMA CELLS BY A FELINE SARCOMA VIRUS. (E.) McAllister, R. M. (U. Southern California Sch. Med. Los Angeles), J. E. Filbert, M. O. Nicholson, R. W. Rongey, M. B. Gardner, R. V. Gilden and R. J. Huebner. *Nature* 230(17):279-282, 1971.

A cell line (MT) derived from a human osteosarcoma was inoculated with feline sarcoma virus (FSV). By 19 days after infection, the FSV-infected cells showed a higher saturation density and a more rounded and tightly packed cell growth than the uninfected MT cultures. Infected MT cells released a virus which induced foci in embryo cells; these foci were similar to foci induced in beagle cell cultures by FSV. C-type particles were seen in FSV-infected MT cells after 3 passages *in vitro*; and infected cells reacted in complement-fixation tests with dog serum against feline C-type virus group specific and envelope antigens. While uninfected MT cells, inoculated into fetal cats, did not cause tumors, FSV-infected MT cells produced s.c. tumors in 2 of 4 cats given these cells. These tumors were fibrosarcomas similar to those induced in cats and dogs by FSV; and the tumors induced in the fetal cats by infected cells contained C-type virus particles.

2299 DNA AND THE RNA VIRUSES. (E.) Spiegelman, S. (Coll. Phys. Surgeons, Columbia U., New York City, N.Y.). *Proc Roy Soc Lond* 177(1046):87-108, 1971.

Incorporation of tritium-labeled thymidine triphosphate into acid-insoluble products were observed with serial transfer preparations of Rous sarcoma virus, Rauscher leukemia virus, feline leukemia virus, avian myeloblastosis virus, Moloney sarcoma virus, murine and monkey tumor viruses. Rous sarcoma virus and Rauscher leukemia virus DNA polymerases maintained linear synthesis for time periods extending to 8 hr, whereas the avian myeloblastosis virus, feline leukemia virus and

murine mammary tumor virus polymerases showed a tendency to slow down after about 90 min. Preparations which did not require pretreatment with detergent to exhibit activity were severely inhibited by the 0.2% detergent required to disrupt the virions. The acid-precipitable product was degraded by DNase but not by RNase, pronase or sodium hydroxide and had a density within the DNA range of 1.450. Results of an annealing reaction between ³H-labeled DNA synthesized with the Rauscher leukemia virus polymerase and a great excess of RNA purified from the virions showed that all the DNA synthesized by the polymerase had some complementarity to the viral RNA. Intermediates of the polymerase reaction isolated after 20 min were found to be DNA-RNA hybrids.

- 2300 DNA POLYMERASE ACTIVITY ASSOCIATED WITH PURIFIED KILHAM RAT VIRUS. (E.) Salzman, L. A. (Natl. Inst. All. Infect. Dis., Natl. Inst. Hlth., Bethesda, Md.). *Nature* 231(3):174-176, 1971.

DNA polymerase which was purified from Kilham rat virus in CsCl gradients showed maximal activity at pH 9 and was inhibited by EDTA, KCl and *p*-chloromercuribenzoate. All 4 deoxynucleotide triphosphates - dGTP, dCTP, dTTP and dATP - were required for maximal DNA polymerase activity. An external source of DNA was also required for maximal enzyme activity, and the enzyme activity increased with increases in enzyme protein. With salmon sperm DNA as a template, the enzyme reaction product was double stranded as judged from its buoyant density in CsCl equilibrium gradients and elution from hydroxyapatite column.

- 2301 VIRUSES AND RENAL CARCINOMA OF *RANA PIPIENS*: XI. ISOLATION OF FROG VIRUS 3 TEMPERATURE-SENSITIVE MUTANTS; COMPLEMENTATION AND GENETIC RECOMBINATION. (E.) Naegele, R. F. (St. Jude Children's Res. Hosp., Memphis, Tenn.) and A. Granoff. *Virology* 44(2):286-295, 1971.

Frog virus 3 was grown in fathead minnow cells and treated with 8×10^{-7} M 5-bromodeoxyuridine; 11 temperature-sensitive mutants were produced of which 6 were studied more fully. Taking the efficiency of plating of the parent frog virus as 1, it was found that the plating efficiency of the mutants at 30° ranged from 1.4×10^{-4} to 3.5×10^{-5} . The number of plaques formed by mutants at 25° ranged from 3.4×10^7 to 3.1×10^8 , while the number of plaques formed by mutants at 30° ranged from 1.2×10^3 to less than 1.0×10^4 . The yield of mutant viruses at 30° was 0.4-3.6% of the yield of mutants at 25°. It was shown that none of the mutants was more temperature-sensitive than wild-type frog virus 3. Five of the mutants studied were found to complement each other in mixed infection experiments; complementation levels ranged from 9-126. High recombination frequencies (e.g., 9-63%) were obtained with all mutants.

- 2302 ULTRASTRUCTURAL AND BIOLOGICAL PROPERTIES OF A CYTOMEGALOVIRUS RESCUED FROM A HUMAN PARANGLIOMA. (E.) Heine, U. (Natl. Cancer Inst. Natl. Inst. Hlth., Bethesda, Md.), J. Kondratieck, D. V. Ablashi, G. R. Armstrong and A. J. Dalton. *Cancer Res* 31(5):542-549, 1971.

When cells from a recurrent human paraganglioma placed in contact with WI-38 cells a virus appeared in the WI-38 cells which had the ultrastructural and antigenic properties of a cytomegalovirus. Original tumor tissue exhibited cells resembling lymphoblasts growing in suspension, and the cells sometimes were seen to contain cytoplasmic areas anastomosing tubular structures in contact with endoplasmic reticulum. The cytomegalovirus in the WI-38 cells produced no cytopathic effect in the cells; it was sensitive to ether treatment. The serum from the paraganglioma patient contained antibodies against cytomegalovirus but no antibodies against herpesvirus hominis or Epstein-Barr virus.

- 2303 CHICK EMBRYO LETHAL ORPHAN (CELO) VIRUS: SOME PHYSICAL AND IMMUNOLOGICAL PROPERTIES. (E.) Potter, C. W. (Dept. Med. Microbiology, U. Sheffield, Yorkshire, England), J. S. Oxford, J. C. Downie, M. M. Attwood and R. D. Hardy. *Virology* 44(2):418-424, 1971.

Chick embryo lethal orphan (CELO) virus was purified from virus-inoculated chicken eggs by equilibrium centrifugation in CsCl density gradients; the virus banded at 1.32 g/cm^3 , and this band was found to contain the peak infectivity virus titers. The thermal denaturation temperature of CELO DNA showed a base composition of 40% guanine-cytosine. CELO complement fixing antigens had the same sedimentation characteristics as did the complement fixing antigens of adenovirus 7. Under the electron microscope, the CELO virus was seen to contain icosahedral particles measuring 60-80 nm in diameter. When an immune serum against CELO was prepared in rabbits and reacted with CELO virus, it was found that the serum reacted with the virus antigens; the serum did not react, however, with adenovirus of various strains. No precipitin lines were formed between CELO antigen and sera prepared against adenovirus 12 antigen in immunodiffusion tests.

- 2304 INFLUENCE OF A LATENT VIRUS ON TRANSCRIPTION OF RNA-METHYLATING ENZYMES. (E.) Wainwright, E. (The New York Blood Ctr., New York). *Cancer Res* 31(5):710-715, 1971.

Cells of *Escherichia coli* K-12 W₆, irradiated with doses of UV light that induced phage development in 90-95% of the cells, were harvested at various intervals after irradiation, and the saturation level of tRNA-methylating capacity of extracts from such cells was measured. Total methylating capacity declined during incubation after irradiation, and a minimum level was reached at about 20 min postirradiation, followed by a rise in methylating activity to pre-

radiation levels. Total tRNA-methylating capacities of *E. coli* B and of several strains of *E. coli* 12 not carrying prophage were unaffected by similar irradiation; experiments with an isogenic pair of organisms with and without prophage also indicated that the transient drop in methylase activity was associated with prophage induction. Dialysates from extracts of UV-induced cells harvested between 10 and 30 min after irradiation inhibited tRNA methylation of extracts of logarithmically growing cells by about 50% indicating that the inhibitory action was the result of metabolic activity which followed UV treatment of prophage-carrying cells.

205 FOREIGN-CELL CONTAMINATION IN BURKITT TUMOURS. (E.) Fialkow, P. J. (Dept. of Pathology, U. Washington, Seattle), G. Klein, E. R. Blott, B. Gothoskar and P. Clifford. *Lancet* (1975):883-886, 1971.

Enzyme phenotypes of Burkitt's lymphomas were compared with those of tissue cultures derived from the lymphomas; the cell markers chosen were glucose-6-phosphatase and phosphoglucomutase. Twenty lymphoma tissue cultures established from 17 tumors from 13 patients with Burkitt's lymphoma were examined. In 6 of the 20 cultures it appeared that the cells were genetically foreign to the host from which they derived; foreign cells may have been present as minor populations in Burkitt's tumors at the time of biopsy. Blood transfusion and laboratory contamination were suggested as sources of the discordant cells.

206 AN INHIBITOR OF HERPESVIRUS HOMINIS IN EXTRACTS OF CULTURES OF BURKITT'S LYMPHOMA. (E.) Rabson, A. S. (Lab. Path., Nat. Cancer Inst., Nat. Inst. Hlth., Bethesda, Md.), S. A. Bressan and F. Y. Legallais. *Proc Soc Exp Biol Med* (1971):264-267, 1971.

Plaque formation in cultures of herpesvirus hominis (HSV)-infected human embryo kidney cells or rat kidney cells was inhibited 3-100-fold when treated with extracts from a jaw tumor of a Nigerian patient with Burkitt's lymphoma. Extracts from the Burkitt's lymphoma did not inhibit plaque formation in vesicular stomatitis virus-infected rat kidney cell cultures to the extent that these extracts inhibited plaque formation by HSV. Burkitt's lymphoma extracts also inhibited viral growth in HSV-infected cultures; titers of HSV in untreated cultures were 10-100-fold higher than in extract-treated cultures. Vesicular stomatitis virus growth was only slightly inhibited in extract-treated cultures. The HSV inhibitor in the Burkitt's lymphoma extract, which was sensitive to trypsin inactivation, did not appear to be interferon or an interferon inducer.

207 CHROMOSOME LESIONS INDUCED IN A HUMAN HEMATOPOIETIC CELL LINE BY INFECTION WITH EPSTEIN-BARR VIRUS. (E.) Huang, C. C. (Springville Labs., Roswell Park Mem. Inst., Springville, N.Y.), J. Minowada and J. S. Horoszewicz. *Proc Soc Exp Biol Med* 137(1):183-190, 1971.

Cell cultures prepared from the peripheral blood of a patient with myelogenous leukemia were inoculated with Epstein-Barr virus (EBV) isolated from a line of Burkitt's lymphoma cells. In uninfected hematopoietic cells from the leukemia patient, the modal chromosome number was 47, the incidence of polyploidy was 2% and a secondary constriction in the center of a D chromosome was seen in 61% of chromosomes studied. Cell viability declined in all cultures following EBV infection, but cultures infected with inactivated virus and uninfected cultures showed no impairment of growth; 96-108 hr postinfection, the number of cells/ml of culture in heat-inactivated EBV-infected cultures, uninfected cultures, and live EBV-infected cultures were 2×10^6 , 1.6×10^6 , and 4×10^5 , resp. EBV-infected cultures retained a modal chromosome number of 47. Chromosome aberrations induced by EBV infection included breaks which were most common in the subterminal and terminal regions. Many chromosomes had minute chromosome material attached to the end of an arm. No dicentric or exchange configurations were seen. Metaphases with pulverized chromosomes were another frequently seen aberration.

2308 MITOCHONDRIAL DNA FROM CELLS TRANSFORMED BY AVIAN MYELOBLASTOSIS VIRUS. (E.)

Riou, G. (Inst. Gustave Roussy, Villejuif, France) and F. Lacour. *Biochimie* 53(1):47-49, 1971.

Three-day-old chickens were inoculated with avian myeloblastosis virus (AMB); 2-3 wk later when the birds were in the terminal stages of leukemia, blood was collected and the mitochondrial DNA of transformed leukemic cells was examined and compared with that of normal cells. Liver and bone marrow cells from leukemic and normal birds were also compared. Examination by electron microscopy revealed that mitochondrial DNA from virus-transformed cells contained 74.4% monomers of circular DNA molecules which were sometimes twisted and sometimes open. Monomers comprised 95-96% of the mitochondrial DNA of normal cells. Virus-transformed cells contained mitochondrial DNA composed of 21.9% dimers and 3.7% catenated oligomers (e.g., trimers, tetramers and pentamers); normal cells had mitochondrial DNA composed of 4-5% dimers and no catenated oligomers.

2309 ALTERED TRANSFER RNA METHYLASE PATTERNS IN MAREK'S DISEASE TUMORS. (E.) Mandel, L.

R. (Merck Inst. Therapeutic Res., Rahway, N. J.), B. Hacker and T. A. Maag. *Cancer Res* 31(5):613-616, 1971.

A correlation was found between tumor development and infection with Marek's disease virus on the one hand and tRNA methylase activity in the liver and kidney of infected chicks on the other. The *in vitro* tRNA methylase activity in liver and kidney

homogenates from Marek's disease virus-infected birds was elevated 3-fold when compared to tRNA methylase activity in noninfected control birds. The tRNA methylase activity was increased in birds which had developed tumors, and was maximal in tumor nodules which were separated from adjacent tissue. Lung, heart and spleen tissue, which were nodule-free, did not show elevated tRNA methylase. Both normal and neoplastic liver were able to methylate heterologous methyl-deficient tRNA from *Escherichia coli*; however, only tumor-bearing liver tissue was able to methylate N⁷-methylguanosine, 3-methylcytidine, and 5-methyluridine.

- 2310 SIZE AND COMPOSITION OF MAREK'S DISEASE VIRUS DEOXYRIBONUCLEIC ACID. (E.) Lee, L. F. (Dept. Microbiology, U. Chicago, Ill.), E. D. Kieff, S. L. Bachenheimer, B. Roizman, P. G. Spear, B. R. Burmester and K. Nazerian. *J Virol* 7(3):289-294, 1971.

DNA was isolated from nucleocapsids of Marek's disease herpesvirus and cosedimented with T4 and with herpes simplex virus DNA in neutral sucrose or alkaline sucrose density gradients. The Marek's disease virus DNA was found to have a sedimentation constant of 56S, which corresponded to a molecular weight of 1.2×10^8 daltons. The most prominent band seen in the alkaline sucrose density gradients contained DNA sedimenting at 70S (molecular weight of 6×10^7 daltons). In hybridization experiments, the Marek's disease virus DNA hybridized with DNA of virus-infected cells but failed to hybridize with RNA of uninfected cells. On isopycnic sedimentation of the Marek's disease virus DNA with SPOL, *M. lysodeikticus* or herpes simplex virus DNA, the virus showed a density of 1.705 g/cm³.

- 2311 VIRAL INTERFERENCE IN FELINE LEUKEMIA-SARCOMA COMPLEX. (E.) Sarma, P. S. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.) and T. Log. *Virology* 44(2):352-358, 1971.

Feline embryo fibroblast (FEF) cultures infected with feline leukemia virus (FeLV) did not show overt signs of morphological transformation; infected cultures contained the FeLV group specific antigen and contained infectious virus. Superinfection of FeLV-infected cultures with related FeLV pseudotypes of murine sarcoma virus and feline sarcoma virus failed to transform the cultures, which appeared to be resistant to superinfection with these viruses; uninfected FEF cultures were susceptible to infection with the pseudotypes. This interference with the FeLV pseudotypes seemed to be specific for FeLV. When pseudotype FeLV of murine sarcoma virus was derived from the same strain of FeLV as that used for the initial infection, viral interference was always observed; however, when the challenge FeLV pseudotype used for superinfection was derived from a strain of FeLV other than the strain used for the initial infection, interference was not always seen.

- 2312 ISOLATION AND CHARACTERIZATION OF TWO GROUP-SPECIFIC ANTIGENS FROM FELINE LEUKEMIA VIRUS. (E.) Schäfer, W. (Max-Planck Tübingen, Germany), J. Lange, D. P. Bolognesi, de Noronha, J. E. Post and C. G. Rickard. *Virology* 44(1):73-82, 1971.

Purified feline leukemia virus was subjected to electrophoresis on polyacrylamide gels with the result that 3 major protein components were identified and designated EI, EII and EIII. EI was more electrophoretically mobile than EII, which was more mobile than EIII. The 3 proteins had molecular weights of 15,000, 18,000 and 33,000, resp. Rat murine leukemia virus had a similar electrophoretic mobility pattern to the feline leukemia virus, as avian leukemia virus had a different pattern. Antigens were isolated from feline leukemia virus which were electrophoretically similar to fractions EI and EIII. The EI isolate was regarded as a specific antigen found only in feline leukemia sarcoma viruses, whereas the EIII protein isolate was regarded as a group-specific antigen occurring in leukemia viruses of animal species other than cat.

- 2313 THE POTENTIAL FOR LEUKEMIA REGRESSION IN BALB/c MICE. (E.) Rich, M. A. (Dept. Biol., Res. Labs., Albert Einstein Med. Ctr., Philadelphia, Penna.) and M. Dietz. *Proc Soc Biol Med* 137(1):35-38, 1971.

ICR/Ha Swiss strain mice and BALB/c strain mice inoculated with conventional and regressing strains of Friend leukemia virus, and the onset and regression of symptoms of leukemia, including splenomegaly, were observed. Both mouse strains were susceptible to leukomogenesis by either strain of virus. Of the Swiss mice given conventional Friend virus, 1 and 8 of 10 given regressing virus developed leukemia with mean latencies of 14 days; all 9 of the BALB/c mice given conventional virus and 7 of 10 given regressing virus developed leukemia with latencies of 12 and 21 days, resp., for the 2 virus strains. 75% leukemia regression was seen among Swiss mice given regressing virus, but none of the BALB/c mice given regressing virus showed regression of leukemia. By 49 days postinfection, 2 of 18 Swiss mice and 1 of 16 BALB/c mice had died with leukemia. When the life span of leukemic BALB/c mice was prolonged by giving them reduced inocula of Friend virus, the mice still failed to show leukemia regression, suggesting that the failure of regression of leukemia in BALB/c mice was not due to the fact that death occurred before expression of regression could occur.

- 2314 TUMOR CELL MIGRATION. (E.) Cochran, A. J. (Karolinska Inst., Stockholm, Sweden). *Rev Europ Etud Biol* 16(1):44-47, 1971.

Cells from an ascitic mouse lymphoma originally induced by Moloney virus were placed in an open capillary tube (10^6 viable tumor cells/tube).

owed to migrate into a planchette containing growth medium. Incubation of the system at 37° increased the migration area; adding 5% CO₂ to the system also increased the area of migration. The area of migration of the tumor cells was decreased by incubation at low temperatures, by placing the tubes at an angle with open end up and by adding actinomycin D or actinomycin C to the system. Killing the tumor cells inhibited the migration of tumor cells altogether.

ANALYSIS OF THE FUSION OF XC CELLS INDUCED BY HOMOGENATES OF MURINE LEUKEMIA VIRUS-INFECTED CELLS AND BY PURIFIED MURINE LEUKEMIA VIRUS. (E.) Johnson, G. S. (Nat'l. Cancer Inst., Bethesda, Md.), R. M. Friedman and I. Pastan. *J Virol* 7(6):753-758, 1971.

Cultures of mouse embryo cells infected with murine leukemia virus were homogenized preparatory to being used as a fusion factor for tissue culture systems of the XC cell line, a Rous sarcoma virus-induced rat tumor. Syncytium formation occurred as a result of the fusion process; an increase in size and number of the multinucleated cells which reached completion within 48 hr was observed. Three general groups were recognized: 1) small multinucleated cells composed of 2-10 nuclei; 2) larger cells composed of about 10-30 nuclei, often accompanied by vacuoles and occasional nuclear fusion; and 3) extremely large cells composed of an indeterminate number of nuclei with extensive nuclear fusion and marked vacuolization. Size and number of cells was dependent upon the amount of fusion factor added. Fusion factor activity was detected in all of the particulate fractions of infected cell homogenates derived from centrifugation up to 35,000 xg but not in the 100 xg supernatant; greatest activity was seen in the 11,000 and 35,000 xg fractions. Trypsin at concentrations as low as 5 µg/ml completely destroyed fusion-stimulating activity whereas ribonuclease, deoxyribonuclease and neuraminidase had no effect.

MURINE LYMPHOMA INDUCED BY REOVIRUS 3. (E.) Phillips, P. A. (Dept. Microbiol., U. Western Australia, Perth), D. Keast, M. Walters and N. F. Stanley. *Pathology* 1:133-138, 1971.

5 mice of the Prince Henry strain inoculated intranasally with 10 LD₅₀ U of reovirus strain HEV, 10 survived the stage of acute virus infection. In 1 of these mice, a large thymic lymphoma with lung infiltration was found. The lymphoma consisted of uniform sheets of lymphocytic cells which completely destroyed the normal architecture of the thymic cells. Reovirus 3 was isolated from circulating leukocytes of the tumor-bearing mouse. Serum from this animal did not contain detectable antibodies to reovirus; reovirus antigen was found in spleen and in the thymic lymphoma. The reovirus-associated thymic lymphoma was transplantable into newborn mice, in which it

grew as a large tumor mass in the mesenteric lymph nodes.

2317 SERINE HYDROXYMETHYL TRANSFERASE ACTIVITY IN EXPERIMENTAL LEUKEMOSIS. (Rus.)

Sergeyev, A. V. (Inst. Exper. and Clin. Oncol. Acad. Med. Sci., U.S.S.R., Moscow), Yu. V. Bukin and M. O. Raushenbakh. *Probl Gemat* 16(3):41-45, 1971.

Spleen tissue of BALB/c mice with Friend virus-induced leukemia had an average 2.25 fold increase in specific serine hydroxymethyltransferase activity compared to controls. The activity of this enzyme in the liver tissue of mice with leukemia was approximately 2 times lower than in the hepatic cells of healthy mice. The *in vitro* sensitivity of serum hydroxymethyltransferase activity to a number of pyridoxal phosphate inhibitors (including hydrazine, hydroxylamine, semicarbazide, thiosemicarbazide, isonicotinylhydrazide and D-cycloserine) in the liver, spleen and ascites cells of mice with experimentally induced leukemia was practically the same for all 3 types of cells and was similar to the sensitivity of this enzyme in the hepatic tissue of healthy mice tested against the same compounds. D-cycloserine (600 mg/kg) administered i.p. twice to mice with experimentally induced Freund's leukemia produced an 87% inhibition of serum hydroxymethyltransferase activity in the splenic tissue and a 98% inhibition of this enzyme in the ascites cells of C57BL mice with Graffi's leukosis.

2318 ELECTRON MICROSCOPIC STUDIES OF TUMOR VIRUSES: I. ENTRY OF MURINE LEUKEMIA VIRUS INTO MOUSE EMBRYO FIBROBLASTS. (E.) Miyamoto, K. (Flow Lab., Inc., Rockville, Md.) and R. V. Gilden. *J Virol* 7(3):395-406, 1971.

Cultures of NIH Swiss mouse embryo cells were treated with 25 µg of DEAE-dextran and subsequently inoculated with Rauscher murine leukemia virus; the entry of the virus into the cells was observed under the electron microscope. As viruses came in contact with the cell membrane the viral envelope was seen to dissolve while the membrane itself remained intact; in other preparations, both the envelope and the membrane dissolved simultaneously as the virus came in contact with the cell, and the viral nucleoids passed into the cell cytoplasm. In some cases, the cell membrane dissolved and the viral envelope remained intact; in these cases, the intact virus particle entered the cell cytoplasm. In the cytoplasm the viral envelope became disrupted permitting release of viral nucleoids into cytoplasm. Viral envelopes were never seen to fuse with cell membranes. The interactions of virus with cell membranes were seen in immature C type virus particles as well as in mature particles.

2319 THE ACTIVATION OF LATENT LEUKEMIC VIRUSES. (Rus.) Mazurenko, N. P. (Inst. Exp. Clin. Oncol. Acad. Med. Sci., U.S.S.R., Moscow), V. I.

Ponomar'kov, Ye. I. Zharova, G. K. Gogichadze, Ye. S. Revazova and N. Ye. Osipov. *Vestn Akad Med Nauk SSSR* 26(3):18-23, 1971.

Splenic and lymphatic tissue from four dogs with reticulosis, reticulo-hemocytoblastosis, hemocytoblastosis and myeloleukosis and from CC57Br mice infected with Mazurenko's hemocytoblastosis reticulosis virus was homogenized, and the suspensions injected i.p. in doses of 2-3 ml/wk into newborn dogs and 0.05-1 ml/wk to newborn mice. Fifteen newborn dogs inoculated with the canine leukosis suspension and six puppies inoculated with mouse leukotic suspensions failed to develop leukemias, despite a 3-yr follow up. In 1 of 8 experimental groups of CC57Br mice inoculated with leukotic suspensions from dogs, 4 of 14 mice (28%) developed leukemia; the incidence of spontaneous leukemias in this strain did not exceed 0.5%. A leukemic virus isolated from the infected mice was identified as Mazurenko's hemocytoblastosis reticulosis virus. Reference is made to a 10-yr experimental period (1957-1967), during which CC57Br mice were found to be latent carriers of the hemocytoblastosis-reticulosis virus which was first activated by the smallpox vaccine virus and subsequently by material from leukemic dogs; the activation mechanism is not known.

2320 SEPARATION OF MURINE CELLULAR AND MURINE LEUKAEMIA VIRUS DNA POLYMERASES. (E.)

Ross, J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), E. M. Scolnick, G. J. Todaro and S. A. Aaronson. *Nature* 231(23):163-167, 1971.

Crude extracts of uninfected and murine leukemia virus-transformed BALB/3T3 cells were tested for DNA polymerase activity with synthetic RNA-DNA or RNA-RNA hybrids as templates. In the normal cell line there were 2 peaks of DNA polymerase activity; peak I had poor activity when poly rA,dT (>100) was used as a template, while peak II responded well. Two peaks of DNA-dependent DNA polymerase activity were eluted from extracts of the transformed cell at the same effluent volumes as those from the normal, uninfected cells, with DNA polymerase peak I eluting slightly ahead of DNA polymerase peak II. Overall yields of activity from uninfected and transformed cells were comparable.

2321 BLOOD ASPARTYL TRANSCARBAMYLASE ACTIVITY IN RAUSCHER VIRUS INDUCED MURINE LEUKEMIA.

(E.) Cory, J. G. (Dept. Chem., U. South Florida, Tampa). *Haematologia* 4(3/4):303-310, 1970.

Mice were infected with Rauscher murine leukemia virus, and aspartyl transcarbamylase (ATC) activity was investigated in their blood; ATC in virus-infected mouse blood was increased 4-fold over ATC in blood of uninfected mice. The Michaelis constants for ATC activity in the blood of normal and virus-infected mice were 1.8×10^{-3} and 1.4×10^{-3} M, resp.; pH activity profiles for ATC in normal and virus-infected mice were also similar. ATC activity in infected mice was inhibited less by succinate and

maleate than ATC in normal mice; the inhibitor constants for succinate was 4-fold larger for blood ATC in infected mice than for blood ATC in uninfected mice. Blood ATC activity in infected mice was markedly more sensitive to the sulfhydryl inhibitors *p*-hydroxymercuribenzoate and *N*-ethylmaleimide than was blood ATC in uninfected mice.

2322 THE ERYTHROCYTE AS VIRUS CARRIER IN FRIEND AND RAUSCHER VIRUS LEUKEMIAS. (E.)

Rauscher, C. A. (Dept. Microbiol., U. Arizona, Tucson) and Schloss. *Cancer Res* 31(6):841-846, 1971.

The response of BALB/c mice inoculated with plasma from various erythrocyte fractions from Friend virus-Rauscher virus-infected animals was measured in terms of mean day of death and degree of infectivity. Blood fractions used were plasma, whole erythrocytes, sonically extracted erythrocytes, sonically extracted erythrocyte stroma, water-lysed erythrocytes, water-lysed erythrocyte stroma and wash medium. The percent infectivity of Friend virus-infected mice in blood fractions ranged from 83-100% and the mean day of death from 43.5-70.3; the sonically extracted water-lysed erythrocyte stroma fractions were the most competent. With Rauscher virus, the degree of infectivity was 23% for the wash medium and 100% for the other fractions; the mean day of death varied from 43.2-75.8. The infected erythrocytes from Friend virus-infected mice showed increased osmotic fragility but not the erythrocytes from Rauscher virus-infected mice. Association of the virus with the erythrocyte could be due to physical adsorption of the virus to the infected plasma or due to infection and transmembrane production of an erythrocyte precursor and subsequent production of virus during maturation to erythrocyte.

2323 COMPLETE FREUND'S ADJUVANT STIMULATION OF RAUSCHER VIRUS-INDUCED LEUKEMOGENESIS.

(Rus.) Ter-Grigorov, V. S. (P. A. Herzen Res. Inst. Oncol. Acad. Med. Sci., U.S.S.R., Moscow), I. S. Irlin, O. Ya. Moskovkina and V. M. Bergol'ts. *Vopr Onkol* 17(2):54-59, 1971.

Freund's complete adjuvant (CFA) administered i.p. (0.1 ml) either 1 wk before or simultaneously with an i.p. injection of Rauscher virus-containing plasma (0.2 ml per animal) stimulated leukemogenesis in a sensitive line of BALB/c mice. Post-mortem examinations indicated increased splenomegaly, increased amounts of leukemic plaques below the splenic capsule, increased viral multiplication and generally earlier mortality of the mice compared with controls infected solely with the Rauscher virus. When administered to mice genetically resistant to the leukemogenic effects of the Rauscher virus, CFA in association with the virus inhibited this resistance and produced two distinct varieties of the pathology in the C57BL/6 strain; in one group inhibition of the leukemogenic resistance was transient and the Rauscher disease regressed, while in other cases irreversible progression of leukemia, sometimes with lympholeukosis, occurred. Four possible hypotheses for CFA stimulation of leukomogenesis are

discussed: a rapid increase in the number of mouse cells sensitive to the leukemogenic viral transformation; stimulation and disruption of the humoral immune response; suppression of the immunological cellular type reaction; inhibition of interferon production.

24 INFECTION OF SIMIAN ADENOVIRUS SA7 IN HAMSTER KIDNEY AND EMBRYO CELLS. (E.) Iino, T. (Res. Inst. Microbial Diseases, Osaka U., Japan) and M. Takahashi. *Biken J* 13(4):303-312, 1970.

Primary hamster kidney (Ham K) and embryo (Ham E) cells, primary African green monkey kidney (AGMK) cells and human embryo kidney and lung cells were inoculated with simian adenovirus SA7 in input multiplicities of 10-50 PFU/cell. In AGMK cells, an increase in infectious virus was seen 24 hr postinfection; at 20 hr postinfection, the virus yield from AGMK cells was $4.5 \log_{10}$ TCID₅₀/ml, while at 48 hr postinfection, the yield was more than $8 \log_{10}$ TCID₅₀/ml. Cytopathic changes were seen in AGMK cells by 13 hr postinfection, and basophilic inclusions were seen in most cells by 24 hr postinfection. Tumor and virus antigens were seen in nearly all AGMK cell nuclei by 24 hr. No significant replication of infectious virus was seen in Ham K or in Ham E cells infected with SA7. Morphological changes induced in Ham K cells by virus included eosinophilic inclusions surrounded by a halo in the nuclei and nuclear degeneration including eosinophilic and basophilic inclusions. Some Ham K cells remained intact through virus infection, and subsequently replicated to give rise to transformed cells. Tumor and viral antigens were seen in the nuclei of 50-60% of Ham K cells and in the nuclei of 20-30% of Ham E cells by 48 hr postinfection. In both Ham K cells and Ham E cells, increased DNA synthesis was seen at an early stage of virus infection; increased viral DNA synthesis was seen at an early stage of virus infection; increased viral DNA synthesis was also observed. Virus replication was seen in infected human cells, but the virus yields were about 1 hundredth of that seen in AGMK cells. Eosinophilic inclusions and basophilic inclusions were seen in human cells by 24 hr postinfection, and tumor and virus antigen were seen in the nuclei by 24 hr postinfection; nuclear degeneration occurred by 58 hr postinfection.

25 THREE SIZE-CLASSES OF INTRACELLULAR ADENOVIRUS DEOXYRIBONUCLEIC ACID. (E.) Worthingham, B. T. (Dept. Cell Biol., Sch. Med. U. Maryland, Baltimore) and W. Doerfler. *J Virol* 7(6):7-719, 1971.

Productive or nonproductive infection of KB cells by human adenovirus 12 (Ad 12) strain Huie or Ad 2 strain Benoit 6 resulted in the synthesis of 3 classes of viral DNA: a class which sedimented in alkaline sucrose gradients > 45S; a species which sedimented with DNA extracted from infectious adenovirions; and a class which sedimented at 18S. Purified adenovir-

ions with ³H-labeled DNA as inoculum permitted the fate of the parental adenovirus DNA to be followed; more than 90% of the label incorporated into the cells was acid precipitable. The fast-sedimenting class of adenovirus DNA that varied between 45-80S (probably due to mechanical breakage of cellular DNA) specifically hybridized with the viral RNA. The hybridization to cellular DNA was variable and ranged from 0.1-5%. Control experiments with recovery of added ¹⁴C-Ad DNA indicated that the fast-sedimenting label from infected cells was comprised of viral genetic material; the complete sensitivity of this material to deoxyribonuclease treatment suggested that this class DNA is uncoated within the cell. An adenovirus DNA which cosedimented with Ad 12 marker DNA also sedimented at 33S in alkaline sucrose gradients and at 29S (34S and 32S for Ad2-DNA) in neutral sucrose gradients; this DNA underwent hybridization only to viral DNA and not to cellular DNA. Essentially all of this class of adenovirus DNA was susceptible to deoxyribonuclease, which indicated that it too was uncoated. The slow-sedimenting DNA also hybridized only to viral DNA and was sensitive to deoxyribonuclease. Correlation of the amounts of label in each DNA class with time indicated that the parental Ad 2 or Ad 12 DNA is cleaved into 18S fragments which may become linked to the fast-sedimenting cellular DNA and serve as precursors to the integrated form of Ad DNA. Inhibition of macromolecular synthesis with thymidine, actinomycin D or cycloheximide had little effect on the formation of the slowly sedimenting species of viral DNA. These results suggest that the 18S viral DNA is not synthesized but is formed by an endonuclease within the cell or the adenovirion.

2326 THE HISTOPATHOLOGY OF TUMORS INDUCED BY PARA-ADENOVIRUS 7 TRANSFORMED CELL CLONES. (E.) Pauluzzi, S. (Inst. Infect. Dis., Perugia U., Italy), R. Ribacchi, R. Frongillo and M. P. Zeppa. *Europ J Cancer* 6(6):537-543, 1970.

Factors contributing to the morphological and antigenic heterogeneity of PARA-adenovirus hybrid-induced tumors were investigated. Two para-cell clones, 819/R/A2a and 928/R/B/Str were isolated from the first *in vitro* passages of PARA-adenovirus 7-induced hamster tumor cells. Both clones induced transplanted tumors similar to primary or transplanted tumors induced by adenovirus 7, adenovirus 12 or simian adenovirus 7 and quite different from SV40-induced tumors. Histological examination revealed undifferentiated small-cell tumors with hemorrhagic necrosis and typical multinucleate giant cells. However, the cell clone 928/R/B/Str revealed both adenovirus T and SV40 T antigens in almost 100% of the cells, while 819/R/A2a cells showed only SV40 T antigen upon immunofluorescence testing. These antigenic characteristics were maintained even after several passages *in vitro*. The uniform morphology of the tumors induced by the 2 investigated PARA-cell clones and the antigenic constancy of these clones indicated that PARA-transformed cells could not differentiate into various morphologic and antigenic phenotypes. Apparently the coexistence of cells which differ morphologically and antigenically in the same PARA-tumor starts from the very beginning of the oncogenic process.

- 2327 ISOLATION OF TEMPERATURE-SENSITIVE MUTANTS OF ADENOVIRUS TYPE 5. (E.) Williams, J. F. (Inst. Virol., Glasgow, Scotland), M. Gharpure, S. Ustacelebi and S. McDonald. *J Gen Virol* 11(2): 95-101, 1971.

Cultures of adenovirus type 5 were treated with either nitrous acid (0.7 M), hydroxylamine (1 M), or 5-bromodeoxyuridine (15 or 30 µg/ml virus culture on HeLa cells). These treatments produced a temperature-sensitive viral mutant strain which showed 1000-fold higher plaque-forming efficiency at 31° than at 38°. The frequency of these mutants in the surviving fractions of virus treated with nitrous acid and hydroxylamine was 8.4 and 9.6%, resp., while the frequency of the mutants in surviving fractions of virus treated with 5-bromodeoxyuridine was 0.55%. Most temperature-sensitive mutants were stable and showed little evidence of leakiness or back mutation.

- 2328 A CYTOCHEMICAL STUDY OF BASIC PROTEINS IN ADENOVIRUS-INFECTED CELLS. (E.) Russell, W. C. (Natl. Inst. Med. Res., London, England), E. Broadaty and J. A. Armstrong. *J Gen Virol* 11(2): 87-93, 1971.

Human embryonic kidney cells were infected at input multiplicities of 200 PFU/cell with adenovirus type 5 and infected cells were stained with phenanthrenequinone and with copper phthalocyanin-neutral red for detection of the presence of arginine in the infected cells. Stained preparations showed ring-like and rosette structures under the microscope; the structures were also seen on staining with fluorescent adenovirus P antiserum. Pretreatment with benzil blocked the cytochemical staining of the adenovirus-infected cells. The rings and rosettes were thought to be sites of arginine accumulation.

- 2329 THE RESPONSE OF BHK21 CELLS TO INFECTION WITH TYPE 12 ADENOVIRUS. V. STIMULATION OF CELLULAR RNA SYNTHESIS AND EVIDENCE FOR TRANSCRIPTION OF THE VIRAL GENOME. (E.) Raska, K., Jr. (Rutgers Med. Sch., Rutgers U., New Brunswick, N.J.), W. A. Strohl, J. A. Holowczak and J. Zimmerman. *Virology* 44(2):296-306

Cultures of baby hamster kidney cells BHK21/13 were infected with adenovirus type 12, and the incorporation of ³H-uridine into cellular RNA was compared in infected and in uninfected cells. BHK21 cells were abortively infected in the G₁ phase of the mitotic cycle. Infected cells showed a 3-5-fold increase in label uptake compared to uninfected cells. Incorporation of label into DNA was 10-15-fold higher in infected cells than in uninfected cells. Uridine kinase activity was found to be increased in the infected cells; the 45S, 32-28S, 18S and 4S species of cellular RNA were all synthesized at an increased rate in infected cells. By 12-14 hr after infection, it could be seen that infected cells were synthesizing virus-specific RNA; this RNA sedimented in the 18S

area of the sucrose gradient, and was thought to be the virus messenger in the cells.

- 2330 THE ULTRASTRUCTURE AND NATURE OF ADENOVIRUS TYPE 2-INDUCED PARACRYSTALLINE FORMATIONS. (E.) Henry, C. J. (William H. Singer Memorial Inst. Allegheny General Hosp., Pittsburgh, Pa.), M. Slifkin, L. P. Merkow and M. Pardo. *Virology* 44(1):215-218, 1971.

Vero or HeLa cell cultures were infected with adenovirus type 2 for 48 or 70 hr and sections of infected cultures were examined under the electron microscope. Infected cells showed crystalline arrays of virus particles, paracrystalline structures and 3 general types of intranuclear inclusion bodies. In some Vero cells, mature virus particles were seen in close association with the periphery of the cytoplasmic crystals. These crystals varied in size and shape. Crystals developed in both the cytoplasm and nucleus of virus-infected Vero cells, whereas crystals were found only in the nucleus of infected HeLa cells. Crystals were eosinophilic but devoid of nucleic acids. Paracrystals were composed of viral capsid antigens.

- 2331 CHROMOSOME TRANSPLANTATION AND TUMOUR ANTIGEN STUDIES OF THREE VIRUS-INDUCED TUMOUR CELL LINES. (E.) Potter, A. M. (Lodge Moor Hosp. Sheffield, England), C. W. Potter and J. S. Oxford. *Arch Ges Virusforsch* 33(1/2):61-71, 1971.

Cell lines derived from hamster tumors induced by adenovirus 12 (Tad III and H212) and by SV40 were inoculated s.c. into hamsters; the cell lines had been passaged more than 200 times *in vitro* and all cells contained specific virus-induced tumor antigens. The SV40-induced tumor cells and the Tad III tumor cells produced tumors in recipient hamsters, while the H212 cell line did not produce tumors in adult hamsters but did produce tumors in newborns. Tad III cells contained relatively low complement fixing titers for tumor antigens while H212 cells contained high complement fixing titers. Marker chromosomes were found to be most common in SV40-induced tumor cells and lowest in H212 tumor cells. Polyploidy was more common in virus-induced tumor cells than in normal hamster cells.

- 2332 STUDIES OF NONDEFECTIVE ADENOVIRUS 2-SIMIAN VIRUS 40 HYBRID VIRUSES: III. BASE COMPOSITION, MOLECULAR WEIGHT, AND CONFORMATION OF THE AD2+ND₁ GENOME. (E.) Crumpacker, C. S. (Natl. Inst. Allergy and Infectious Diseases, Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), E. Henry, T. Kakefuda, W. P. Rowe, M. J. Levin and A. Lewis, Jr. *J Virol* 7(3):352-358, 1971.

The nondefective hybrid of SV40 and adenovirus 2, designated Ad2+ND₁, was found to contain DNA with a buoyant density of 1.715 g/cm³ and a thermal denaturation profile of 75.1 C; both these values were

closely similar to those calculated for the DNA of nonhybrid adenovirus 2. The molecular weight of 12^+ND_1 DNA was found to be about 22×10^6 to 25×10^6 daltons and that of adenovirus 2 itself was 13×10^6 to 25×10^6 . All the DNA molecules in 12^+ND_1 virus were double-stranded and linear. It was estimated that the hybrid virus contained about one-tenth of the SV40 genome, or 220×10^3 to 250×10^3 daltons of SV40 DNA.

333 SOME INDICATORS OF CARBOHYDRATE METABOLISM IN TISSUE CULTURE, IN PRIMARY CONTACT WITH ONCOGENIC VIRUSES AND IN SARCOMAS INDUCED BY ADENOVIRUS-12. (E.) Ageenko, A. I. (Hertzen Res. Inst. Oncol., Moscow, U.S.S.R.) and N. Kholmukhamedova. *Biia Biol (Praha)* 17(1):13-17, 1971.

The dynamics of carbohydrate metabolism following primary contact with oncogenic or infectious virus were investigated in Wistar rat embryo cell monolayer cultures. Human adenovirus type-12, -3 or -6 grown in cell culture was used in a dose of 10^3 - 10^4 TCID₅₀/0.1 ml (tissue culture infectious dose). Aerobic and anaerobic glycolysis rates appeared to be highest in the adenovirus-type-12-infected cell cultures reaching maximal values at 40 hr after inoculation. Enhanced oxygen consumption was maximal 4 hr following inoculation with all 3 types of adenovirus returning to normal values at 120 hr after the beginning of the experiment. Aldolase and lactate dehydrogenase activities were highest in the adenovirus type-12-infected cultures with maximal plateau values between 48-72 hr and 96-168 hr following inoculation. The infectious titer of adenovirus type-3 and adenovirus type-6 increased during the 1st hr and reached maximal values 72 hr following inoculation; no such increase was observed with adenovirus type 12.

334 PERSISTENT INFECTION WITH HERPES SIMPLEX VIRUS *IN VITRO*. II. EFFECT OF ANTIBODY ON THE COURSE OF HERPETIC PERSISTENCY IN EARLE'S CELLS. (E.) Nii, S. (Res. Inst. Microbial Diseases, Osaka U., Japan). *Biken J* 13(4):339-352, 1970.

Cultures of Earle's L cells persistently infected with herpes simplex virus were grown in medium containing either human antiserum or human γ globulin; the spread of the cytopathic effect in infected cultures was reduced by the antibody treatment, and after 1 month in culture no cytopathic foci were to be seen in the infected cells. However, virus persisted in the cells in most cultures for 1-8 months. Subcultures of infected cells treated with antibody retained virus even when grown in antibody-containing medium in the course of subculturing. In cells subcultured without antibody, cytopathic changes appeared earliest in fresh cultures. In some infected cultures without antibody, infectious virus and cytopathic changes were not detected until a latent period had elapsed. Although virus spread in Earle's L cells in the presence of antibody was

arrested, virus spread in BSC1 cells infected with virus in the presence of antibody was not as markedly suppressed.

2335 GUINEA PIG LEUKOCYTES; *IN VIVO* AND *IN VITRO* INFECTION WITH A HERPES-LIKE VIRUS. (E.) Hsiung, G. D. (VA Hosp., West Haven, Conn.), C. K. Y. Fong and K. M. Lam. *J Immunol* 106(6):1686-1689, 1971.

Hartley strain guinea pigs were given inoculations of 10^6 TCID₅₀/ml of a Herpes-like virus (HLV) suspension, and the animals were killed thereafter and leukocyte cultures were prepared and examined by electron microscopy. In some cases guinea pig leukocytes were infected *in vitro* with HLV. Although HLV particles were seen in leukocytes established in 3-day cultures from infected animals, no virus particles were found in leukocytes taken directly from infected guinea pigs. When guinea pigs leukocyte cultures were infected *in vitro* with HLV, it was found that there were more viable leukocytes in the infected cultures than in the control uninfected cultures.

2336 TRANSFER OF THYMIDINE KINASE TO THYMIDINE KINASELESS L CELLS BY INFECTION WITH ULTRAVIOLET-IRRADIATED HERPES SIMPLEX VIRUS. (E.) Munyon, W. (Roswell Park Mem. Inst., Buffalo, New York), E. Kraiselburd, D. Davis and J. Mann. *J Virol* 7(6):813-820, 1971.

Herpes simplex virus (HSV) suspensions were exposed to UV for 1-18 min in amounts of 23 ergs/mm²/second; irradiated virus was used to infect cultures of L₁ cells which lacked thymidine kinase activity (Ltk⁻ cells). The transformation of Ltk⁻ to Ltk⁺ cells in virus-infected cultures was measured by the formation of colonies of Ltk⁺ cells in a supplemented growth medium. No colony formation was observed with uninfected L cells, or with cells infected with unirradiated HSV, but colony formation was seen with cultures infected with irradiated HSV; the maximum frequency of Ltk⁻ to Ltk⁺ transformation was about 10^{-3} . Cell lines of HSV-transformed Ltk⁺ cell lines contained 7-24 times as much thymidine kinase activity as did parental Ltk⁻ cells. Optimal formation of Ltk⁺-transformed cell colonies was seen in cultures infected with HSV which had been irradiated with UV for 9-12 min. The number of Ltk⁺-transformed colonies formed was proportional to the dose of virus. Substitution of bromodeoxyuridine for thymidine in the supplemented growth medium, which was infected with irradiated HSV, suppressed colony formation. A mutant strain of HSV which failed to induce thymidine kinase activity during lytic infection failed to cause the Ltk⁻ to Ltk⁺ transformation. This transformation may have been caused by the transfer of a viral gene to the Ltk⁻ cells; alternatively, the transformation may have been caused by the promotion of expression of a repressed cellular enzyme by a product of the viral gene.

- 2337 DEOXYRIBONUCLEIC ACID SYNTHESIS IN SYNCHRONIZED MAMMALIAN KB CELLS INFECTED WITH HERPES SIMPLEX VIRUS. (E.) Cohen, G. H. (Center for Oral Hlth. Res., U. Pennsylvania, Philadelphia), R. K. Vaughan and W. C. Lawrence. *J Virol* 7(6): 783-791, 1971.

Mammalian KB cells were infected with herpes simplex virus (HSV) at various times after synchronization of cells by double thymidine block; an unscheduled round of viral DNA synthesis occurred 2-3 hr after infection of the synchronized cells, regardless of the time in the cell cycle that the infectious virus was introduced. In a related experiment, synchronized KB cells were infected with HSV at 3, 5, 8, and 11 hr after reversal of the thymidine block and the time-course of infectious virus formation was observed. In each case, increases in progeny virus were seen 6 hr postinfection, with maximum titers of virus occurring 11-12 hr postinfection. A similar cycle of viral replication was seen in all infected cultures without regard to the time of virus infection relative to the mitotic phase of the cells. When KB cells were infected with HSV at a time when host cell DNA synthesis was minimal (11 hr after the beginning of cell synchrony), viral DNA synthesis began 2-3 hr postinfection; viral DNA synthesis attained maximum levels by 4 hr postinfection and dropped off by 8 hr postinfection. HSV infection may have inhibited synthesis of KB cell DNA and the initiation of the S phase of mitosis.

- 2338 VIRUSES AND RENAL CARCINOMA OF *RANA PIPPIENS*: X. COMPARISON OF HERPES-TYPE VIRUSES ASSOCIATED WITH LUCKE TUMOR-BEARING FROGS. (E.) Gravell, M. (St. Jude Child. Res. Hosp., Memphis, Tenn.). *Virology* 43(3):730-733, 1971.

The base compositions of Rafferty isolate (frog virus 4, FV4) DNA and herpes-type virus (L-HTV) DNA from Lucke tumors were estimated from their melting profiles. The guanine plus cytosine (G + C) contents calculated from the T_m values for FV4 and L-HTV DNA were 54% and 45%, resp. The base composition of FV4 DNA estimated from its equilibrium buoyant density in $CsCl_2$ was 56% G + C; FV4 DNA banded at a density of 1.715 g/ml. DNA:DNA hybridization studies to detect homologous sequences with DNA from FV4, L-HTV, cultured adult frog kidney cells and a polyhedral cytoplasmic DNA virus showed that FV4 DNA hybridized with homologous DNA up to 70.6% but less than 1.56% with any heterologous DNA. Virus neutralization tests with FV4 and L-HTV antisera showed no cross-reactivity between the 2 viruses, further indicating that FV4 and L-HTV are different viruses.

- 2339 SYNERGISTIC EFFECT OF HERPES SIMPLEX VIRUS AND CYTOSINE ARABINOSIDE ON HUMAN CHROMOSOMES. (E.) O'Neill, F. J. (Milton S. Hershey Med. Ctr. Pennsylvania State U., Hersey, Pa.) and F. Rapp. *J Virol* 7(5):692-695, 1971.

Logarithmically growing human embryonic lung cells were inoculated with herpes simplex virus type 2

(5 PFU/cell) together with 10 μ g of cytosine arabinoside (ara-C). Of 225 cells examined after treatment with virus (strain 333) and ara-C, 9 cells had 1 chromosome break, 7 cells had 2 breaks and 78 cells had 3 or more breaks. In addition, 27 cells showed secondary constrictions. In human embryonic lung cells treated with herpes simplex virus alone, 15 cells had 1 chromosome break, 4 had 2 breaks and 1 had 3 or more breaks, while 33 cells had secondary constrictions. In cells treated with ara-C alone, 37 cells had 1 chromosome break, 13 had 2 breaks and 13 had 3 or more breaks, while 3 cells had secondary constrictions. Cells not treated with either virus or ara-C had 4 cells with 1 break, 1 cell with 2 breaks and no cells with 3 or more breaks, while 2 cells showed secondary constrictions. It was thought that herpes simplex virus and ara-C acted synergistically to promote chromosome changes in the human lung cells.

- 2340 IN VITRO INDUCTION OF A HERPES-TYPE VIRUS IN "SUMMER-PHASE" LUCKE TUMOR EXPLANTS. (E.) Breidenbach, G. P. (Dept. Microbiol., Tulane U., New Orleans, La.), M. S. Skinner, J. H. Wallace and M. Mizell. *J Virol* 7(5):679-682, 1971.

Tumor cells from a Lucké "summer phase" renal adenocarcinoma of *Rana pipiens* were incubated at 15.5°, 11.5° or 7.5°C for 8-14 wk. The Lucké "summer phase" tumor developed at 22°-26°C on frogs collected during the summer and on frogs maintained in the laboratory; a "winter phase" tumor form was found on frogs during the cooler months and on frogs maintained in the laboratory at or below 7.5°C. 14 of the 6 explants from the summer phase tumors kept at 7.5°C, 3-5% of the nuclei were seen to be enlarged by 14 wk in culture and 1% of the cells showed type A virus particles. Empty or complete herpes virus particles were seen in the nuclei of cells kept at 7.5°C.

- 2341 LYMPHOID CELL-CULTURE LINE DERIVED FROM LYMPH NODE OF MARMOSET INFECTED WITH HERPESVIRUS SAIMIRI--PRELIMINARY REPORT. (E.) Rabson, A. S. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth. Bethesda, Md.), G. T. O'Connor, D. E. Lorenz, R. L. Kirschstein, F. Y. Legallais and T. S. Tralka. *J Nat Cancer Inst* 46(5):1099-1103, 1971.

Marmoset monkeys infected with *Herpesvirus saimiri* developed malignant lymphoma, and a lymphoid cell line designated MLC-1 was derived from the lymph node of affected marmosets. Three months after initiation of the cell culture very few MLC-1 cells containing intranuclear herpesvirus particles were found, and virus could not be isolated from frozen and thawed MLC-1 cell pellets or culture supernatants. However, a herpesvirus could be isolated from cell cultures produced by co-cultivation of MLC-1 cells with Vero monkey kidney cells. This herpesvirus produced smaller plaques than *H. saimiri* and appeared to be antigenically related to that virus. In MLC-1 cultures of 5 mo. standing the *H. saimiri*-like virus could occasionally be isolated from cell supernatants. When inoculated into marmoset

sets, the *H. saimiri*-like virus produced a malignant condition similar to that produced by *H. saimiri*; however, the condition produced by the *H. saimiri*-like virus was characterized by more necrosis and less lymphoreticular cell proliferation than was seen in marmosets infected with *H. saimiri* itself.

- 2342 EARLY EVENTS REQUIRED FOR INDUCTION OF CHROMOSOME ABNORMALITIES IN HUMAN CELLS BY HERPES SIMPLEX VIRUS. (E.) O'Neill, F. J. (Milton S. Hershey Med. Ctr., Pennsylvania State U., Hershey) and F. Rapp. *Virology* 44(3):544-553, 1971.

When logarithmically growing cultures of human embryonic lung cells were infected overnight with 2 or 5 PFU of herpes simplex virus (HSV), the number of cells with chromosome aberrations was significantly increased in comparison to uninfected cells. Abnormalities observed in virus-infected cultures included chromosome breaks, secondary constrictions and erosion. When cells were pretreated with human interferon prior to virus infection, the incidence of chromosome abnormalities in infected cultures did not exceed that in uninfected cells, suggesting that chromosome abnormalities are induced by virus infection following the uncoating of the viruses, and that the induction of aberrations requires some translation of the viral genome. When cytosine arabinoside (10 µg/ml) or iododeoxyuridine (25 to 100 µg/ml) were added to cell cultures following virus infection, virus multiplication in the infected cells was inhibited by more than 99.9%; however, neither cytosine arabinoside nor iododeoxyuridine inhibited the induction of chromosome abnormalities by HSV. Apparently, viral induction of chromosome aberrations occurs at a period preceding viral DNA synthesis. Cytosine arabinoside appeared to potentiate the induction of aberrations by HSV.

- 2343 LYMPHOID CELL LINES: ACTIVATION OF A LATENT HERPES-LIKE VIRUS PARTICLE? (E.) McCormick, K. J. (Baylor Coll. Med., Houston, Tex.), D. M. Mumford, W. A. Stenback and J. J. Trentin. *Nature* 230(11):83-84, 1971.

Antigenic conversion of 2 lymphoid cell lines grown *in vitro* is described. One cell line was derived from a patient with Burkitt's lymphoma and cultured for 6 months (11 passages) before the presence of herpes virus particles or of complement fixing (CF) antigen could be ascertained. Another cell line derived from a child suspected of having infectious mononucleosis revealed the presence of herpes-like virus particles and indirect immunofluorescence (IF) antigen after 2.5 yr of cell culture. By that time the cells became positive by CF with African sera. These antigenic conversions seem to indicate that the genetic information for virus production is carried in apparently virus-negative cell lines.

- 2344 MOUSE MAMMARY TUMORIGENESIS BY MAMMARY TUMOR VIRUS IN THE ABSENCE OF THYMUS, SPLEEN OR BOTH ORGANS. (E.) Squartini, F. (Med. Sch., U. Pisa, Italy). *Israel J Med Sci* 7(1): 26-35, 1971.

Mice of various strains underwent thymectomy at 1 day-of-age or splenectomy at 2 days-of-age, or both operations; all the mice strains used except one carried a spontaneous infection with mammary tumor virus (MTV). In a group of female BALB/c (MTV-free) mice injected with MTV after undergoing thymectomy, 39% of animals developed hyperplastic alveolar mammary nodules, whereas the percentage of intact mice developing nodules in groups given MTV was 100%; the percentage of intact mice developing nodules in groups not given MTV was 20%. The incidence of pregnancy-dependent mammary tumors or plaques was observed in BALB/cf(RIII) MTV-infected mice; in intact mice, mammary tumors were pregnancy-dependent to some degree in 81.5% of the cases, whereas in thymectomized mice, tumors were partially pregnancy-dependent in only 23% of the cases. In intact BALB/cf(C3H) mice frank mammary tumors developed in 82% of cases, whereas thymectomized mice of the same strain developed lesions in 46% of cases. Thymectomy also prolonged the latent period for the appearance of these tumors. In force-bred mice the incidence of mammary tumor development was similar to that in intact mice. Thymectomy did not affect the frequency of mammary tumors in RIII strain mice. In splenectomized BALB/cf(C3H) mice, the incidence and latency of mammary tumor development was reduced; tumors developed in 82% of intact mice and in 52% of splenectomized mice. In mice of this strain which underwent both thymectomy and splenectomy, splenectomy partially suppressed the depressive effect of thymectomy on tumor development; splenectomized and thymectomized mice had tumor incidence patterns similar to those seen in intact mice. Splenectomy did not affect tumor incidence in RIII strain mice.

- 2345 POSSIBILITY OF A DNA-CONTAINING MAMMARY TUMOR VIRUS IN RED BLOOD CELLS OF MOUSE. (E.) Nandi, S. (Dept. Zool., U. California, Berkeley). *Nature* 230(13):146-147, 1971.

The RBC fraction was separated from the blood of 6-8 wk old BALB/cfC3H mice infected with mammary tumor virus and incubated with various proteases and nucleases for 2 hr at 37° either singly or in combination. Neither proteases nor nucleases were able to destroy the infectivity of the RBC fraction; however, the addition of RNase or DNase following treatment with protease caused complete inactivation. However, when DNase or RNase was previously treated with a nuclease inhibitor, the effect was lost. These results demonstrate the nucleoprotein nature of the infective moiety designated as R-MTV.

- 2346 INHIBITION OF SPONTANEOUS MAMMARY CARCINOMA OF MICE BY TREATMENT WITH INTERFERON AND POLY I:C. (E.) Came, P. E. (Dept. Microbiol., Schering

Corp., Bloomfield, N. J.) and D. H. Moore. *Proc Soc Exp Biol Med* 137(1):304-305, 1971.

Strain RIII mice were given 100 µg doses of polyinosinic acid:polycytidylic acid (poly I:C), 1000-2500 U interferon, normal mouse serum or no treatment (control), and the incidence of mammary tumor development and the appearance of mammary tumor virus in mammary milk were observed in the 4 treatment groups. Normal mouse serum did not reduce the incidence of spontaneous tumors from that seen in the control group; by 35 wk after treatment, nearly 100% of the control mice had tumors, and nearly 100% of mice given normal serum had tumors. Poly I:C and interferon both inhibited the rate of tumor development; by 35 wk after treatment, only 60% of mice given poly I:C had developed tumors and a similar percentage of interferon-treated mice had developed tumors. Milk samples from mice in all 4 treatment groups were positive for mammary tumor virus.

- 2347 DISTRIBUTION OF VIRAL ANTIGEN IN MOUSE MAMMARY TUMOR CELLS AS REVEALED BY FERRITIN ANTIBODY CONJUGATE TECHNIQUE. (E.) Okano, H. (Fac. Med., Kyushu U., Fukuoka, Japan). *Acta Path Jap* 21(1):57-66, 1971.

Type B virus particles were isolated from a spontaneous C3H mouse mammary carcinoma and used to inoculate male rabbits for the purpose of obtaining an antiserum against the B type particles. The antiserum was conjugated with ferritin and allowed to penetrate frozen slices of mouse mammary tumor, which contained A virus particles as well as B particles. Ferritin granules were found deposited on type B particles and on budding A particles; some ferritin granules were seen on the naked cytoplasmic A particles. On the basis of the localization of the ferritin granules, it was thought that type A virus particles and type B particles share some antigenic property.

- 2348 STUDIES ON MICE OF A TUMOR RESISTANT STRAIN (X/Gf): VIII. TYPE C PARTICLES IN MAMMARY TUMORS OF FRIEND LEUKEMIA VIRUS-INFECTED MICE. (E.) Goldfeder, A. (The Mount Sinai School of Med. of the City U. of New York, New York), E. de Harven and C. Friend. *Rev Europ Etud Clin Biol* 16(4):323-328, 1971.

Mice of strain X/Gf, which do not develop spontaneous neoplasms and which are resistant to tumor induction by irradiation, were infected with Friend leukemia virus at different ages. Eight of 11 mice infected before 3 wk of age developed leukemia, while only 5 of 15 mice infected at more advanced ages developed leukemia. Mice surviving the initial virus infection were divided into 2 groups: one group was given 400 r of X-irradiation at intervals of 53-103 days after virus infection while the other group was not given X-irradiation. Mice in the irradiated and virus-infected group developed malignant lymphoma and lymphatic leukemia in some cases, while mice infected with virus but not given X-irradiation developed malignant lymphoma, reticulum cell sarcoma, and in some cases hepatoma. Two female mice

treated with both radiation and virus infection developed mammary adenocarcinoma. Mammary tumors were found to contain C type virus particles similar to particles associated with murine leukemia.

- 2349 ANTIGENICALLY DISTINCT FORMS OF MAMMARY TUMOR VIRUS IN BLOOD AND MAMMARY TISSUE OF MICE. (E.) Nandi, S. (Dept. Zool., U. Calif. Berkeley), S. Haslam and C. D. Aldrich. *J Natl Cancer Inst* 46(5):1035-1038, 1971.

Mammary tumor virus (MTV) antigens from mammary tissue or milk from BALB/cfC3H/Crg1 (C⁺) mice with Freund's adjuvant were used to immunize syngeneic adult female C⁺ mice and New Zealand White rabbits by i.p. injection on day 1 and without adjuvant on days 30 and 68. The mice were bled on day 90 and pooled sera from 3 separate sets of rabbits were heat-inactivated by incubation at 56°C for 30 min subsequently adsorbed *in vitro* with RBC from MTV- (C⁻) mice. Both mouse and rabbit antisera against MTV neutralized mouse MTV but not rabbit MTV. Of mice injected with virus incubated with antiserum against B particles and tumor extracts from C⁺ mice 7% developed an average of 2 nodules per mouse, whereas 34 of 39 mice, or 87% developed an average of 19 nodules in the control groups. In contrast rabbit MTV incubated in the same antisera induced an average of 31 nodules per mouse among 26 of 37 mice or 70% compared to an average of 25 nodules among 27 control mice, or 63%. Results indicate that MTV activity in mammary tissue extracts, but not hemolyzed RBC preparations, can be neutralized by syngeneic or allogeneic mouse or rabbit antisera against virus preparations from milk or mammary tumors.

- 2350 DEMONSTRATION OF DIFFERENCES IN MURINE SARCOMA VIRUS FOCI FORMED IN MOUSE AND CELLS UNDER A SOFT AGAR OVERLAY. (E.) Levy, J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *J Natl Cancer Inst* 46(5):1001-1006, 1971.

Cultures of mouse embryo cells and rat kidney cells were infected on soft agar overlay media with murine sarcoma virus. In the mouse cells, the virus produced foci of infection which released both murine sarcoma virus and murine leukemia virus; however transformed mouse cells could not be subcultured. Foci of virus infection in rat cells generally did not yield either sarcoma virus or leukemia virus unless the cultures were superinfected with leukemia virus. Foci in rat cells could be subcultured.

- 2351 *IN VIVO* ENHANCEMENT OF A MURINE SARCOMA VIRUS BY DIETHYLAMINOETHYL-DEXTRAN. (E.) Gazdar, A. F. (Nat. Cancer Inst., Nat. Inst. Hlth., Bethesda, Md.), E. Russell and R. H. Bassin. *Proc Soc Exp Biol Med* 137(1):310-314, 1971.

Mice of the NIH Swiss strain were administered injections of DEAE-dextran in association with inoculations of Moloney murine sarcoma virus (MSV) and

effect of the DEAE-dextran treatment on the tumorigenicity of the virus inoculum was observed. When 200 µg of DEAE-dextran was inoculated together with the virus, the latency period for tumor appearance was shortened; in addition a 10-fold enhancement was seen in the minimal dose of virus required to induce tumors. DEAE-dextran-treatment reduced the number of regressing tumors developed by treated mice. When mice were given 200 µg DEAE-dextran 1 hr before inoculation with virus, pretreated mice developed tumors earlier than did mice not treated with DEAE-dextran. Pretreated mice developed tumors earlier than did mice given DEAE-dextran and virus simultaneously; latent periods for the 2 groups were 6.4 and 8.1 days, resp. The addition of a murine leukemia virus helper virus to the MSV did not affect the latency for virus-induced tumor development, with or without DEAE-dextran treatment.

2352 COMMON GENETIC ALTERATIONS OF RNA TUMOUR VIRUSES GROWN IN HUMAN CELLS. (E.)

Aaronson, S. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Nature* 230(5294):445-447, 1971.

Factors contributing to the occurrence of host range alterations in murine sarcoma viruses grown in human cell cultures were investigated. A human fibroblast strain derived from a skin biopsy of a healthy subject, BALB/3T3 and NIH/3T3 mouse cell lines and normal rat kidney (NRK) cell lines were subjected to transformation by purified strains of Kirsten murine sarcoma virus (KiMuSV/KiMuLV) or Rouschke murine leukemia virus (R-MuLV). The Kirsten virus consisted of 2 strains, one transforming (KiMuSV) and one non-focus-forming helper murine leukemia virus (KiMuLV). All transformed cell lines were propagated through 4-16 generations. After continued cell passages for several wk the released sarcoma viruses lost their ability to transform mouse NIH/3T3 cells and virus replication became more intense in human cells; equal focus inducing capability in human fibroblasts and in NRK cells was then observed. No change in host range could be noticed when KiMuSV/KiMuLV was grown in either NRK or NIH/3T3 cells for long periods. Further tests indicated that both the sarcoma and leukemia viruses of the Kirsten group had undergone a genetic modification during their growth in human cells. However, human or NRK cells infected with either of the altered viruses developed murine viral group specific antigens detectable by complement fixation indicating that these viruses maintained their murine character. Neutralization studies with each of the genetically altered viruses revealed that antisera against human R-MuLV or KiMuSV/KiMuLV were potent inhibitors of focus-formation. In contrast, neither antiserum infected the parent virus strain, indicating that common surface antigens not detectable in the original virus stocks existed in the genetically altered viruses.

2353 ISOLATION OF A RAT-TROPIC HELPER VIRUS FROM M-MSV-0 STOCKS. (E.)

Aaronson, S. A. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Virology* 44(1):29-36, 1971.

A non-focus-forming virus was isolated from the M-MSV-0 strain of rat Moloney murine sarcoma virus grown on normal rat kidney cells; the new virus had properties of a leukemia helper virus. The host range of the new virus was similar to that of M-MSV-0; it transformed rat cells but not mouse cells; furthermore, the new virus could be neutralized by antiserum to M-MSV-0. The new virus was able to transform normal rat kidney cells in the absence of leukemia virus but was unable to produce detectable virus or viral antigens in the absence of leukemia virus. The unusual host range and antigenicity of M-MSV-0 were thought to be expressions of the new virus, and it was suggested that the new virus may be an indigenous virus of the rat.

2354 INDUCTION OF SUGAR UPTAKE BY A HAMSTER PSEUDOTYPE SARCOMA VIRUS. (E.)

Hatanaka, M. (Flow Lab. Inc., Rockville, Md.), R. V. Gilden and G. Kelloff. *Virology* 43(3):734-736, 1971.

Hamster embryo cell cultures were infected with a pseudotype virus having the envelope and internal virion antigens of a hamster C-type virus and the sarcoma genes of the Moloney strain murine sarcoma virus [M-MSV(HaLV)], and the rate of sugar uptake by the cultured cells was determined. Secondary cultures of hamster embryo cells were inoculated with M-MSV(HaLV) and HaLV helper virus. A greatly enhanced rate of ^{14}C -D-glucose was observed in the sarcoma virus-infected cells compared to non-infected controls or helper virus-infected cells. The enhanced uptake occurred along with the first appearance of morphologically altered cells and seemed to be dependent on the actual transformation process. Cells infected with helper virus became resistant to superinfection with sarcoma virus at 7 days and were actively producing virus as revealed by uridine labeling and density gradient studies. Determination of the kinetic constants for glucose uptake showed an approximate 10-fold decrease in K_m for infected cultures without a similar dramatic change in V_{max} . The induction of sugar uptake parallels that seen in mouse cells infected with murine sarcoma viruses, suggesting that the sarcoma genes in the hamster pseudotype virus are responsible for the enhanced sugar uptake.

2355 VIRUS SPECIFIC RNA IN CELLS TRANSFORMED BY RNA TUMOUR VIRUSES. (E.)

Green, M. (Saint Louis U. Sch. Med., Mo.), H. Rokutanda and M. Rokutanda. *Nature* 230(16):229-232, 1971.

Highly radioactive Harvey murine sarcoma virus (MSV-H) ^3H -DNA was annealed with RNA from MSV-H transformed mouse cells (MEH cell line) or with RNA from normal mouse cells; the amount of product was measured by cesium sulfate density gradient centrifugation and by chromatography. Seventy percent of the DNA label from transformed cells was found in the hybrid position, demonstrating the presence of virus specific RNA, while no hybrid was seen in control cells. Hydroxyapatite chromatography revealed that 12-73% of hybrids were formed from nuclear RNA and that about 14-56% of hybrids were formed from cytoplasmic

(S-30) RNA, compared to values of 15-65% from nuclear RNA and 37-53% from cytoplasmic RNA with the use of cesium sulfate gradients; more hybrids were formed with larger concentrations of RNA. Cells cryptically transformed by RNA tumor viruses which contain no detectable infectious virus, gave a maximum hybrid yield of 30% compared to the maximum 73% yield in transformed cells that replicate virus.

- 2356 ANTIGENIC DIFFERENTIATION OF M-MSV(0) FROM MOUSE, HAMSTER, AND CAT C-TYPE VIRUSES. (E.) Gilden, R. V. (Flow Lab. Inc., Rockville, Md.), S. Oroszlan and R. J. Huebner. *Virology* 43(3):722-724, 1971.

A virus isolated from a female BN rat inoculated with the Moloney strain of murine sarcoma virus was analyzed antigenically in complement-fixation and gel diffusion assays with guinea pig antiserum for the mouse and hamster major group-specific determinants and with dog serum having anti-gs-1 antigen of feline C-type viruses. Positive fixation was not seen at a 1:4 dilution with guinea pig and dog sera containing gs-1 antibodies; negative results were also obtained with gel diffusion. Serum pool obtained from rats immunized with murine sarcoma virus transplant tumors readily detected the common antigen in the virus isolated from the rats and other C-type preparations.

- 2357 DEOXYRIBONUCLEIC ACID POLYMERASE OF ROUS SARCOMA VIRUS: STUDIES ON THE MECHANISM OF DOUBLE-STRANDED DEOXYRIBONUCLEIC ACID SYNTHESIS. (E.) Faras, A. (Dept. Microbiology, U. California, San Francisco), L. Fanshier, A.-C. Garapin, W. Levinson and J. M. Bishop. *J Virol* 7(5):539-548, 1971.

The mechanism of DNA synthesis *in vitro* by Rous sarcoma virus polymerase was examined. A preliminary model was established which included 4 basic features of the reaction so far elucidated. The initial event consists of the formation of a DNA:RNA hybrid in which short segments of single-stranded DNA are synthesized utilizing 70S RNA as template. DNA contained in this hybrid is partially accessible to digestion by a single strand-specific endonuclease indicating that the hybrid possesses branches of single-stranded DNA. This single-stranded DNA serves as a template and precursor for the synthesis of double-stranded DNA. The synthesis of double-stranded DNA appears to occur in association with viral RNA. Double-stranded DNA could not be formed until after its release from the hybrid. Disruption of the hybrid by hydrolysis with RNase in low concentrations of electrolytes resulted in the partial isolation of single-stranded DNA. Synthesis of DNA seems to be effected by an undisturbed series of enzymatic reactions which may approximate the circumstances that follow viral infection.

- 2358 COMPARISON OF ROUS SARCOMA VIRUS-SPECIFIC DEOXYRIBONUCLEIC ACID POLYMERASES IN VIRIONS OF ROUS SARCOMA VIRUS AND IN ROUS SARCOMA VIRUS-INFECTED CHICKEN CELLS. (E.) Coffin, J. M. (McArdle Lab., U. Wisconsin, Madison) and H. M. Temin. *J Virol* 7(5):625-634, 1971.

Chick embryo fibroblasts were infected with Rous sarcoma virus, and infected cultures were labeled with ^3H -uridine or ^3H -leucine; virus was harvested from cultures and virion cores were prepared by disruption of viruses. When virions were examined on sucrose density gradients, a core fraction was found which had a density of approximately 1.24. This fraction contained all of the uridine label about a third of the leucine label. Endogenous viral DNA polymerase activity was confined to the density fraction. Both RNA and DNA dependent DNA polymerases were found at the top of the density gradients. When Rous virus-infected chicken cells were subjected to density gradient centrifugation, RNA and DNA dependent DNA polymerase were present in infected cells. These polymerases were also found in particles released from disrupted infected cells; these particles contained viral RNA and had densities greater than 1.30 g/cc.

- 2359 TRANSFORMATION BY ROUS SARCOMA VIRUS: EFFECTS ON CELLULAR GLYCOLIPIDS. (E.) Hakomori, S.-I. (Dept. Pathobiol., U. Washington Med., Seattle), T. Saito and P. K. Vogt. *Virology* 44(3):609-621, 1971.

Four kinds of sialosylglycolipids, 1 neutral glycolipid and a ceramide were found in chick embryo fibroblast cell cultures. The sialosylglycolipids included hematoside (SL-1), disialosylhematoside (SL-2), monosialosyl glycolipid mixture (SL-3) and disialosyl glycolipid mixture (SL-4). Chick embryo fibroblast cells were infected with Rous sarcoma viruses, including Schmidt-Ruppin Rous virus, Rous associated virus and Prague strain Rous virus. It was found that the SL-2 and SL-3 contents decreased drastically in cells infected with Prague strain Rous virus or with a pseudotype of fusiform Rous virus, while the contents of ceramide and neutral glycolipid usually increased by more than 100%. In chick embryo fibroblast cultures infected by Rous associated virus, little change was seen in the cellular glycolipid contents. Turnover rates for SL-1, SL-2 and SL-3 were accelerated in cell cultures transformed by Prague strain virus and pseudotype Rous virus; cell cultures infected by Rous-associated virus did not show an appreciable change in rate of glycolipid turnover relative to the rates for uninfected control cultures.

- 2360 SUBCUTANEOUS TUMOURS INDUCED BY BRYAN STRAIN CHICKEN ROUS SARCOMA IN THYMECTOMIZED AND ALS-TREATED HAMSTERS. (E.) de Haller, F. (Cancer Inst., U. Louvain, Belgium). *Neoplasia* 18(1):33-39, 1971.

ryan strain Rous sarcoma virus derived from chickens was injected s.c. into hamsters less than 1 day of age; the hamsters were previously thymectomized or given antilymphocyte serum (ALS). In some cases, ALS was administered 7 days after virus inoculation and in some cases ALS was administered prior to virus infection. Virus inocula consisted of 0.2 ml of undiluted virus. None of the control hamsters (no thymectomy and no ALS) developed tumors. However, 100% of the thymectomized hamsters developed tumors within 1 month of inoculation. Tumors were s.c. carcinomas, sometimes fibrosarcomatous, but more often undifferentiated and could be serially transplanted in adult hamsters. Hamsters given ALS 7 days after virus infection did not develop tumors; however, hamsters given ALS prior to virus infection developed tumors in 70% of cases within 10-20 days post-infection. While most of the tumors in the thymectomized group eventually regressed, tumors in the ALS group contained high titers of virus and often progressed, causing death.

361 REVERSION IN VIRUS-TRANSFORMED CELLS. (E.) Macpherson, I. (Imperial Cancer Res. Fund, London, England). *Biochem Pharmacol* 20(5):1005-1008, 1971.

The Schmidt-Ruppin strain of Rous sarcoma virus was found to transform hamster cells *in vitro*, but a few cell colonies among the transformed cells retained the characteristics of the untransformed line (revertant cells). Revertant cells in these cultures apparently did not possess the viral genome; transformed cells showed high colony-forming efficiency, induced tumors in hamsters, and contained an avian leukosis virus-group specific antigen. Virus could be recovered from transformed cells. By contrast, revertant cells had minimal colony-forming efficiency, were only slightly effective in inducing tumors in hamsters and lacked the group specific antigen. Revertant cells did not permit the recovery of virus. While hamster cells infected with Rous sarcoma virus produced revertant cells spontaneously, hamster cells infected with and transformed by polyoma virus did not; nevertheless, revertant cells appeared in polyoma virus-transformed cultures following the induction of chromosome loss from a line of nearly triploid hamster cells transformed by polyoma. Both revertant Rous sarcoma virus-transformed cells and revertant polyoma virus-transformed cells could be retransformed by the respective viruses.

362 NATURE OF RIBONUCLEASE-RESISTANT NUCLEIC ACID OF CHICK EMBRYO CELLS TRANSFORMED BY SCHMIDT-RUPPIN STRAIN OF ROUS SARCOMA VIRUS. (E.) Borelli, K. K. (Rockefeller U., New York, N. Y.). *Nature* 229(1):25-27, 1971.

The mode of replication of oncogenic viral RNAs was studied by investigating the presence of RNase-resistant RNA structures in chick embryo cells transformed by Schmidt-Ruppin Rous sarcoma virus (SR-RSV). The RNase-resistant nucleic acid isolate (peak I NA) had an absorption maximum at 258 nm and a minimum at

230 nm and a ratio of light absorption at 280 nm/260 nm of 0.5. The total radioactivity ($5\text{-}^3\text{H}$ -uridine) of this material constituted approximately 0.54% of the total radioactivity of the cellular nucleic acids. Peak I NA was not affected by the combined actions of RNase A and RNase T₁ or by normal NaOH; however, it was rendered acid-soluble by prolonged digestion (4 hr) with pancreatic DNase at 37°C in a Tris-HCl (pH 7.45) buffer. When peak I NA was hydrolysed and its purines and pyrimidines separated, 97% of the radioactivity appeared to be associated with cytosine and only 0.4% with uracil. When subjected to equilibrium density centrifugation in CsCl solution, the nucleic acid banded at a density of 1.695 g/ml. Peak I NA contained 17.2 guanine, 28.9 adenine, 24.9 cytosine and 29.0 thymine (moles %), when purified by centrifugation in CsCl solution; it contained no uracil, and its base composition was similar to that of healthy chick embryo cellular DNA. The radioactive cytosine from peak I NA must have been derived from $5\text{-}^3\text{H}$ -uridine. The resistance of peak I NA to NaOH, its susceptibility to DNase and the conversion of $5\text{-}^3\text{H}$ -uridine to the cytosine moiety suggest no evidence for the existence of RNase-resistant RNA in chick embryo cells transformed by SR-RSV; the RNase-resistant NA of peak I material apparently was DNA.

2363 FURTHER STUDIES ON MAMMALIAN CELL STRAINS TRANSFORMED BY AVIAN SARCOMA VIRUSES. (E.) Smidova, V. (Slovak Acad. Sci., Bratislava, Czechoslovakia) and J. Smida. *Neoplasma* 17(6):595-600, 1970.

Avian sarcoma virus strains such as the Schmidt-Ruppin strain of the Rous sarcoma virus (SR-RSV), B77V, the Fujinami sarcoma virus (FSV) and the Bryan standard RSV (BS-RSV) were used to investigate the oncogenicity and the presence of viral genome in transformed mammalian (rat embryo) cells after cloning. Two cell strains, B77R and PB, were established following transformation *in vitro* with B77Y; cell strain SR was established following transformation with SR-RSV, while the FR strain was obtained by transformation with FSV. The B77R and SR cell strains contained the viral genome specified by B77V and SR-RSV. The 2 other cell strains (PB and FR) appeared to be oncogenic for rats and did not contain the viral genome. Oncogenicity and the presence of the viral genome as well as the morphology and growth pattern of the transformed cells remained unaltered upon long-term cultivation *in vitro*. Clonal cell lines from the B77R and SR cell strains proved to have the same features. B77V and SR-RSV could be rescued from B77R and SR clones by intracerebral inoculation into 1-day-old chicks; they showed the same host range in ducklings and Japanese quail as the original viral strain. No virus reproduction in the B77R and SR cell strains could be induced.

2364 BHK CELLS DOUBLY TRANSFORMED BY ROUS VIRUS AND POLYOMA VIRUS: KARYOLOGICAL STUDY. (E.) Berebbi, M. (Regional Anti-Cancer Ctr.,

Marseille, France) and H. Bonneau. *Rev Europ Etud Clin Biol* 16(3):246-250, 1971.

Karyological studies were performed on normal baby hamster kidney fibroblasts (strain BHK 21/13), on BHK 21/13 cells transformed by Rous sarcoma virus (Bryan strain), on BHK 21/13 cells transformed by the polyoma virus, on BHK 21/13 cells transformed by Rous sarcoma virus (Schmidt-Ruppin strain) and polyoma virus, on BHK 21/13 cells transformed by Rous sarcoma virus (Bryan strain) and polyoma virus, and on BHK 21/13 cells transformed by Rous sarcoma virus (Bryan strain) and irradiated polyoma virus. Normal BHK 21/13 cells and polyoma virus-transformed cells had a modal chromosome number of 44; however, cells transformed by Rous sarcoma virus (Bryan strain) were hypotetraploid. All clones of cells transformed by Rous virus as well as by polyoma virus were diploid or pseudodiploid in chromosomal mode. A subline of BHK 21/13 cells transformed by Rous virus and irradiated polyoma virus was hypotetraploid, having a mode of 70-72 chromosomes. No specific chromosomal structural anomalies were found to be induced in BHK 21/13 cells transformed by Rous sarcoma virus and/or polyoma virus; however, marker chromosomes were found in the cells transformed by the irradiated polyoma virus.

- 2365 ONCOGENICITY OF THE RIBONUCLEIC ACID EXTRACTED FROM CHICKEN SARCOMA INDUCED BY THE CARR (ZILBER) STRAIN OF ROUS SARCOMA VIRUS (RSV-CARR/ZILBER/-RNA) IN MICE. (Fr.) Nastac, E. (Acad. Med. Sci., Bucharest, Rumania), M. Lungu, P. Athanasiu and M. Stoian. *Ann Histochem* 15(4): 273-282, 1971.

RNA, extracted from a chicken sarcoma induced by the Carr (Zilber) strain of Rous sarcoma virus (RNA Carr RSV), was inoculated into randombred white mice to test its oncogenicity in mammals. A phenolic extract containing 200-300 µg/ml RNA was given to newborn mice (0.2 ml s.c.), to pregnant mice during the last 4 days of pregnancy (0.5 ml i.p.), and to adult mice (s.c. or intracerebrally). Similar groups were inoculated with an RNase-treated (10 µg/ml for 30 min at 37°C) RNA extract (negative control) or with a suspension of avian tumor cells (ATC) at a 1:20 dilution (positive control). The mice treated with RNA Carr RSV or ATC developed generalized adenoid hypertrophy, solid tumors of the lung or considerable hepatosplenomegaly; RNase-treated extracts did not show any oncogenicity. The induced neoplasia was transmissible in both cases (2-4 passages). Microscopy revealed intense proliferation of the alveolar epithelium and infiltration of lymphoblastic cells in the lung, diffuse infiltration of the sinusoidal spaces with lymphoblasts and dystrophic alterations of the hepatocytes in the liver, and a considerable lymphoid proliferation within the adenoid and spleen tissues. The i.m. inoculation of tumor cell suspensions from these mice to 3-wk-old white leghorn chickens induced sarcomas typical for the RSV strain used in the experiment.

- 2366 RELATIONSHIP BETWEEN INITIATING DOSE AND CONCENTRATION OF ROUS SARCOMA VIRUS (TYPE 0) IN TUMORS OF GERM-FREE QUAIL. (E.) Bryan, W. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda Md.), M. R. Sacksteder, R. D. Schwartz, J. P. Kvedar, P. K. Vogt and J. Warren. *J Nat Cancer Inst* 46(5):1093-1097, 1971.

Germ-free Japanese quail 20-40-days-old were inoculated with Rous sarcoma virus type 0 (RSV(0)) derived from chick embryo fibroblasts originally infected with chick tumor extracts. Virus dilutions of 10^{-5} produced a sarcoma incidence of less than 25% in inoculated birds, while dilutions of 10^{-3} to 10^0 produced 100% tumor incidence. A correlation was found between the tumor incidence produced by various virus dilutions and the log titer of virus recoverable from tumors. Virus dilutions of 10^{-5} produced log titers of less than 2.0 of recoverable virus, while dilutions of 10^{-2} to 10^0 produced log titers of 6-7. Plasma of chicks bearing tumors induced by RSV(0) were free of neutralizing antibody against that virus.

- 2367 COMPARATIVE STUDY OF ROUS VIRUS VARIANTS ISOLATED FROM MURINE ROUS SARCOMAS AND THE ORIGINAL CARR-ZILBER STRAIN. (Rus.) Kryukov, I. N. (N. F. Gamalaya Inst. Epidem. Microbiol. Acad. Med. Sci., U.S.S.R., Moscow), I. B. Obukh and F. Tot. *Vop Virus* 16(1):92-97, 1971.

Syngeneic mouse embryo cells were infected by but not transformed by Rous virus-induced tumors when inoculated into adult mice. The Rous virus variants isolated from these tumors differed from the original Carr-Zilber strain in their oncogenicity for adult mice and in their decreased capacity to produce transformation foci in chick embryo chorioallantoic membranes (CAM), regardless of the presence or absence of antigens belonging to the original strain as shown by cross neutralization tests. The investigated Rous virus variants (K-3, Af₁₃, IaAf, Af₂₅, SHC₃H, CC₅₇Br, C₃H) produced transformation foci with characteristic morphology in CAM; the virus isolated from the foci appeared to be oncogenic in adult mice. The original Carr-Zilber strain also acquired carcinogenicity for adult mice following passage on CAM.

- 2368 DNA LIGASE AND EXONUCLEASE ACTIVITIES IN VIRIONS OF ROUS SARCOMA VIRUS. (E.) Mizutani, S. (McArdle Lab. Cancer Res., U. Wisconsin-Madison), H. M. Temin, M. Kodama and R. T. Wells. *Nature* 230(16):232-235, 1971.

Incubation of disrupted virions of Schmidt-Ruppin avian sarcoma virus with 32 P-poly d(IC)-d(IC) resulted in a decrease in the amount of acid insoluble 32 P in the absence of bacterial alkaline phosphatase; subsequent incubation of the virions with 5 mM phosphatase did not inhibit this reaction. Chromatography of the products of the reaction showed that both 5'-dIMP and 5'-dCMP were formed. Exonuclease activity

was demonstrated to be dependent upon divalent cations and was inactivated by heating; no inhibition was seen with P-chloromercuribenzoate. An increase in bacterial alkaline phosphatase resistant ^{32}P was found with time; the reaction was roughly proportional to the amount of disrupted virions in the reaction mixture, was dependent upon the presence of a divalent cation and showed greater activity in the presence of manganese than in magnesium. The ^{32}P product of the ligase reaction was hydrolyzed either by micrococcal nuclease and spleen phosphodiesterase or by pancreatic DNAase I and venom phosphodiesterase.

- 2369 STRUCTURAL POLYPEPTIDES OF SIMIAN VIRUS 40. (E.) Estes, M. K. (School Med., U. North Carolina, Chapel Hill), E.-S. Huang and J. S. Pagano. *J Virol* 7(5):635-641, 1971.

Simian virus 40 (SV40) was grown in animal cells and purified prior to analysis by electrophoresis on polyacrylamide gels containing sodium dodecyl sulfate (SDS). The purified virus was seen to contain 6 virion proteins (VP1-6) with molecular weights ranging from 11,000-43,000. VP1 had a molecular weight of 43,000 and contained 70% of the virus protein, VP2 had a molecular weight of 32,000 and contained 9% of the virus protein, VP3 had a molecular weight of 23,000 and contained 10% of the virus protein, VP4 had a molecular weight of 14,000 and contained 6% of the virus protein, VP5 had a molecular weight of 12,500 and contained 4% of the virus protein, and VP6 had a molecular weight of 11,000 and contained 3% of the virus protein. Empty virions contained reduced amounts of VP4, 5 and 6. On velocity centrifugation of degraded SV40, VP1 and VP2 remained at the top of the centrifuge gradient, while VP4, 5 and 6 sedimented as a complex with the viral DNA. VP3 was found in association with VP1 or with the smaller polypeptides. It was thought that the latter formed the nucleoprotein of the SV40 virion, and that VP1 and VP2, which comprised about 80% of the virus protein, formed the virus capsid. VP3 may have represented an intermediate component.

- 2370 INDUCTION OF CELL DIVISION IN MEDIUM LACKING SERUM GROWTH FACTOR BY SV40. (E.) Smith, J. S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), C. D. Scher and G. J. Todaro. *Virology* 44(2):359-370, 1971.

BALB/3T3 mouse cells were infected with SV40; the cells had been grown in a culture medium which lacked protein growth factors necessary for cell division. Despite the lack of growth factors, SV40 infection induced cell division in the mouse cells; by 5 days after infection, colonies containing 8 or more cells were seen in infected cultures. The number of cell divisions induced in infected cultures was proportional to the input multiplicity of virus infection. When SV40 was exposed to an infectivity-inhibiting dose of UV, the capacity of virus to produce growth in the factor-free medium was reduced,

which suggested that the viral genome was needed to induce cell division. Transformation by SV40 of cells in factor-free medium was apparently not permanent; 36 of 57 colonies induced to divide by SV40 did not contain SV40 T antigen. In addition, few of the SV40-transformed cells grew to high saturation density when shifted to a complete growth medium. One SV40-transformed clone which was able to grow in factor-free medium displayed strong contact inhibition despite its production of SV40 T antigen.

- 2371 STUDIES OF NONDEFECTIVE ADENOVIRUS 2-SIMIAN VIRUS 40 HYBRID VIRUSES: II. RELATIONSHIP OF ADENOVIRUS 2 DEOXYRIBONUCLEIC ACID AND SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID IN THE $\text{Ad2}^+\text{ND}_1$ GENOME. (E.) Levin, M. J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), C. S. Crumpacker, A. M. Lewis, Jr., M. N. Oxman, P. H. Henry and W. P. Rowe. *J Virol* 7(3):343-351, 1971.

A hybrid virus which was able to replicate without the presence of a nonhybrid adenovirus helper was isolated from an adenovirus 2-SV40 hybrid population; the nondefective adenovirus was designated $\text{Ad2}^+\text{ND}_1$. The DNA from $\text{Ad2}^+\text{ND}_1$ was obtained free of nonhybrid adenovirus DNA and was shown by RNA-DNA hybridization tests to consist of nucleotide sequences which were complementary to adenovirus 2 and to SV40-specific RNA. Equilibrium density and rate zonal centrifugation indicated that these nucleotide sequences were linked together in the same DNA molecules by alkali-resistant bonds. It was estimated that about 1% of the $\text{Ad2}^+\text{ND}_1$ DNA consisted of SV40 nucleotides.

- 2372 MALIGNANT TRANSFORMATION *IN VITRO* BY "NON-ONCOGENIC" VARIANTS OF DEFECTIVE SV40 (PARA). (E.) Butel, J. S. (Baylor Coll. Med., Houston, Texas), S. S. Tevethia and M. Nachtigal. *J Immunol* 106(4):969-974, 1971.

Lung and kidney cells from weanling male Syrian hamsters of the LSH/ssLAK inbred strain were found to undergo transformation *in vitro* when inoculated with 4 variants of the PARA (defective SV40)-adenovirus that was "non-oncogenic" for newborn hamsters *in vivo*. The multiplicity of infection ranged from 1.3 to 9 plaque-forming units with latency periods ranging from 2 to 7 wk. The cell lines transformed by the non-oncogenic variants of PARA could not be distinguished in tissue culture from those transformed by oncogenic viruses and were found to contain SV40 T and S antigens upon immunofluorescence testing. Transplantability of these cells into syngeneic weanling hamsters at concentrations of 10^6 or 10^5 cells/animal varied; most of the transformed lung cells induced tumors *in vivo* with latency periods ranging between 4-10 wk except for one cell line that produced tumors in 1 of 10 hamsters 14 wk after inoculation. The transformed kidney cell lines elicited a wide spectrum of transplantability, and it was not possible to conclude whether lung or kidney cells are better indicators

of the oncogenic potential of PARA-adenoviruses. All the cell lines established following transformation by oncogenic variants of PARA were readily transplantable *in vivo*. Sera collected from hamsters bearing tumors induced by the defective para-transformed cell lines contained antibody against adeno T antigens in 16 of 35 cases and antibody against SV40 T antigens in 28 of 35 cases.

- 2373 QUANTITATION OF SIMIAN VIRUS 40 SEQUENCES IN AFRICAN GREEN MONKEY, MOUSE, AND VIRUS-TRANSFORMED CELL GENOMES. (E.) Gelb, L. D. (Natl. Inst. Allergy and Infectious Dis., Natl. Inst. Hlth., Bethesda, Md.), D. E. Kohne and M. A. Marten. *J Mol Biol* 57(1):129-145, 1971.

Simian virus 40 (SV40) DNA prepared from infected African green monkey kidney, BSC-1 or Vero cells, DNA from homogenates of normal green monkey, 3T3 and hamster SV40 tumor cell, and salmon sperm DNA were used to study hybridization and re-association kinetics. No significant reaction occurred between labeled SV40 DNA and the immobilized green monkey DNA. In 4 of the 5 SV40-transformed lines examined, the SV40 genome equivalents per mammalian diploid cell ranged from 1.04-3.86, with the large value present in only 1 line.

- 2374 SV 40 VIRUS TRANSFORMED PROSTATIC CARCINOMA IN THE HAMSTER: II. COMPARISONS OF LACTATE DEHYDROGENASE ISOENZYMES WITH HUMAN PROSTATIC CANCER. (E.) Abdalla, A. M. (Roy. Victoria Hosp., Montreal, Quebec, Canada) and J. A. Oliver. *Invest Urol* 8(5):488-493, 1971.

The electrophoretic mobility patterns of the lactate dehydrogenase isoenzyme (LDH) of an SV40-induced hamster prostatic carcinoma and of a human prostatic carcinoma were compared. Tumor tissues and serum samples from hamster and human were prepared by centrifugation and subject to electrophoresis on agarose gel. Both human and hamster tumor tissue showed 5 distinct fluorescent areas of electrophoretic activity. Whereas in human prostatic carcinoma, the fifth fraction of LDH migrated toward the cathode, thus indicating that it is positively charged, the fifth fraction of LDH in the hamster tumor migrated toward the anode, thus indicating that it is negatively charged.

- 2375 SUSCEPTIBILITY OF TRISOMIC AND OF TRIPLOID HUMAN FIBROBLASTS TO SIMIAN VIRUS 40 (SV40). (E.) Payne, R. E. (Sch. Pub. Hlth., U. Michigan, Ann Arbor) and R. D. Schmickel. *Nature* 230(14):190, 1971.

Fibroblast cultures from human subjects were infected with SV40; triploid human cells (69 XXY), human cells with G trisomy, cells from patients with Fanconi's anemia and normal cells were studied. The susceptibility of the fibroblasts was measured by the proportion of cells producing SV40 T antigen. Among normal

cells, 8.8% produced T antigen and among Fanconi's anemic cells, 39.8% produced T antigen. Among triploid human cells, 8.8% produced viral T antigen and among G-trisomic human cells, 18.1% produced T antigen, suggesting that the increased viral susceptibility of trisomic cells results from factors other than the mere presence of an extra chromosome.

- 2376 INCREASED TRANSFORMATION EFFICIENCY OF SIMIAN VIRUS 40 IN RAT EMBRYO CELLS INFECTED WITH RAUSCHER LEUKAEMIA VIRUS. (E.) Rhim, J. S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), C. Greenawalt, K. K. Takemoto and R. J. Huebner. *Nature* 230(11):81-82, 1971.

Rat embryo cell cultures infected with Rauscher leukemia virus (RLV) and uninfected cultures were infected with SV40 at input multiplicities of 10^5 to $10^{8.2}$ PFU/culture plate. By 24 days after infection, the average number of transformed foci/plate in cultures not infected with RLV ranged between 10-100, while the average number of transformed foci/plate in cultures infected with RLV ranged from 10-110. SV40 tumor antigen was detected in the nuclei of 1-5% of RLV-infected cells and in 1-5% of the nuclei of uninfected cells. The complement fixing antigen titer against murine sarcoma virus rat antiserum was greater than 1:4 in RLV-infected cells and less than 1:4 in uninfected cells.

- 2377 APPARENT DIFFERENCES IN TRANSCRIPTIONAL CONTROL IN CELLS PRODUCTIVELY INFECTED AND TRANSFORMED BY SV40. (E.) Sauer, G. (German Cancer Res. Inst., Heidelberg). *Nature* 231(22):135-138, 1971.

Experiments were carried out to demonstrate the relationship between synthesis of late SV40 mRNA sequences and DNA replication using arabinofuranosylcytosine (ara-C) as an inhibitor of DNA replication. In a hybridization competition experiment, labeled late SV40 mRNA was added to immobilized DNA, and unlabelled SV40 mRNA was included in the reaction mixture in increasing amounts. While late SV40 mRNA extracted 3 hr after infection did not seem to contain SV40-specific sequences, early SV40 mRNA sequences which appeared 6 hr after infection displayed 25% homology with late SV40 mRNA. This homology remained unchanged up to 17 hr after infection. After 19.5 hr new SV40 mRNA sequences were present, which competed with late ^3H -SV40 mRNA. The presence of ara-C in the infected cultures prevented the transcription of new sequences of the viral genome. An experiment to determine whether transcription of early genes was sequential or whether all early genes were being copied simultaneously was performed. It was found that early SV40 genes were transcribed simultaneously during the early period of infection. Ara-C inhibited completely transcription of late SV40 mRNA sequences. It was concluded that DNA replication is a requirement for transcription of late SV40 genes in a productive cycle of infection.

78 DNA REPLICATION IN SV40-INFECTED CELLS:
V. CIRCULAR AND CATENATED OLIGOMERS OF
SV40 DNA. (E.) Jaenisch, R. (Dept. Biochem.,
Princeton U., Princeton, N.J.) and A. Levine.
Virology 44(3):480-493, 1971.

Extracellular viral ^3H -DNA from African monkey
cells infected with simian virus 40 (SV40) was
analyzed by gradient centrifugation and investi-
gated for infectivity. Fraction I sedimented in
alkaline sucrose gradients as a single symmetrical
peak at the position of monomeric SV40 DNA, while
fraction II contained 3 distinct peaks of radio-
activity with the main peak corresponding to the
monomeric viral DNA, 30% sedimenting at a position
expected for double length SV40 DNA, and a third
peak at the position expected for denatured
single-stranded dimers. Fractions III and IV
revealed a considerable amount of monomers, dimers
and other heterogeneous molecules. Electron micro-
scopy revealed circular molecules of various con-
former lengths and various combinations of catenated
molecules; either one or both submolecules were
released by DNase treatment. All fractions were
infectious and the relative infectivity with re-
gard to SV40 DNA (set at 1.0) was 0.5, 0.14, and
0.85 for fractions II', III', IV' (dialyzed
fraction II, III, IV), resp.

79 COMPARISON OF CYTOCIDAL AND NONCYTOCIDAL
STRAINS OF SHOPE RABBIT FIBROMA VIRUS.

(E.) Hinze, H. C. (U. Wisconsin Med. School,
Madison) and D. L. Walker. *J Virol* 7(5):577-581,
1971.

Seven strains of fibroma virus, including Shope
fibroma virus strains 1, 289, 384 and 472, the
original Patuxent strain, the Boerlage strain and
the M1 strain, were used to infect rabbit kidney
cells in culture (1-5 PFU/cell) and the growth of
cells infected with the various virus strains was
compared. All virus strains except M1 produced
similar responses in infected cultures; cell counts
in infected cultures increased from about 10^5 to
about $10^{5.5}$ - $10^{5.7}$ cells/culture within 11 days after
infection. In cultures infected with the M1 virus
strain, cell counts dropped to zero by day 8 post-
infection. The cytotoxic M1 virus strain was found
to differ significantly from a noncytotoxic strain
in rate of virus multiplication, plaque type,
genetic properties or heat lability. Viruses of
various strains produced similar tumors when
injected into rabbits.

80 VIRUS MULTIPLICATION IN CULTURE CELLS SYN-
CHRONIZED BY EXCESS THYMIDINE TREATMENT:
EFFECT OF VIRAL DNA SYNTHESIS OF SHOPE FIBROMA
VIRUS AND COWPOX VIRUS UPON NUCLEAR DNA SYNTHESIS
IN SYNCHRONIZED FL CELLS. (E.) Mantani, M. (Res.
Inst. Microbial Diseases, Osaka U., Japan) and S.
O. *Biken J* 13(4):365-376, 1970.

Cells were synchronized by double excess thymidine
treatment and infected at different stages of the

mitotic cycle with Shope fibroma virus or cowpox
virus; autoradiographic techniques were used to
determine the effect of viral DNA synthesis on
nuclear DNA synthesis in the infected cells. Cellu-
lar DNA synthesis was abolished in cells in which
viral DNA synthesis was going forward in the G_1 phase,
and cellular DNA synthesis was partially inhibited
in cells in which viral DNA synthesis was going for-
ward in the S phase. Both viruses produced similar
effects on cellular DNA synthesis.

2381 ENZYME HISTOCHEMISTRY IN SHOPE PAPILLOMA:
HISTOCHEMICAL OBSERVATIONS OF ENZYMES IN
SHOPE PAPILLOMATOSIS OF THE RABBIT SKIN. (E.) Mori,
M. (Osaka U. Dent. Sch., Japan), M. Morishita, Y.
Yoshimura, T. O. Yoshida and Y. Ito. *Ann Histochem*
15(4):297-310, 1970.

Adult rabbits were infected with Shope papilloma
virus by the scarification method on 8 dorsal sites,
and tissue specimens obtained from hyperplastic skin
and papillomatous growths at the sites of introduc-
tion of the virus were assayed for enzyme activity.
Alkaline phosphatase activity was lacking in normal,
hyperplastic and tumorous epithelium; capillary
vessels, however, were positive for alkaline phos-
phatase. Keratinized regions of infected tissue
were strongly positive for acid phosphatase activity.
Esterase activity was absent in normal epithelium
but present in neoplastic papilloma cells. Amino-
peptidase activity was slight in the stroma of deep
tumors of the dermis. Papillomas and normal tissue
had similar levels of β -glucuronidase. Glucose-6-
phosphatase activity increased during the growth of
papillomas. Succinate dehydrogenase was slight in
papilloma cells, while lactate and glucose-6-
phosphate dehydrogenases were at high levels in
tumor cells.

2382 MULTIPLICATION OF POLYOMA VIRUS IN MOUSE-
HAMSTER SOMATIC HYBRIDS: A HYBRID CELL
LINE WHICH PRODUCES VIRAL PARTICLES CONTAINING PRE-
DOMINANTLY HOST DEOXYRIBONUCLEIC ACID. (E.)
Basilico, C. (New York U. Sch. Med., New York, N. Y.)
and S. J. Burstin. *J Virol* 7(6):802-812, 1971.

When cells of a mouse-hamster somatic hybrid line,
3T3 x BHK (10A), were infected with polyoma virus,
the cells synthesized polyoma virus T antigen, as
did infected 3T3 mouse cells; comparable frequencies
of 10A and 3T3 cells produced virus. However, 10A
cells produced less than 1% of the amount of infec-
tious virus produced by the 3T3 cells. The incor-
poration of ^3H -thymidine into polyoma virus DNA in
10A cells was 5% of that seen in 3T3 cells. Viral
DNA produced in 10A cells was normal in size,
buoyant density and infectivity, but the polyoma
virus particles produced by infected 10A cells were
for the most part noninfectious. The titer of
hemagglutination U in infected 10A cells was
26,000-55,000 U, while titers in infected 3T3 cells
reached 400,000 U. DNA-DNA hybridization experi-
ments indicated that DNA from infected 10A cells
consisted of less than 10% viral DNA and 90%
cellular DNA.

2383 PROPERTIES OF POLYOMA VIRUS TRANSFORMED CELLS: I. ONCOGENIC PROPERTIES. (E.)

Babiuk, L. A. (Dept. Microbiol., U. British Columbia, Vancouver, Canada) and J. B. Hudson. *Canad J Microbiol* 17(6):747-751, 1971.

Three- or 5-wk-old hamsters were given injections s.c. of polyoma virus-transformed hamster cells or polyoma virus itself, and the incidence of tumors produced was observed. It was found that passage of virus-transformed cells *in vivo* resulted in an increase in oncogenicity; the latency of tumor appearance was decreased and as few as 5 or 10 transformed cells were sufficient to produce tumors in hamsters. The time required for induction of tumors following an s.c. dose of transformed cells was directly related to the age of the recipient hamster; tumors appeared 10 days earlier in 3-wk-old animals than in 5-wk-old animals. A direct positive correlation was also seen between number of cells injected and tumor latency. Tumors produced by s.c. injection of virus-transformed cells appeared only at the site of injection and never metastasized. Injections of 10^7 PFU of polyoma virus caused tumors throughout the hamsters. Tumors caused by polyoma virus usually showed more mitotic figures and more anaplastic tissue than did tumors caused by polyoma virus-transformed cells, which were comparatively benign. No oncolytic activity was seen when the arbovirus Powassan was grown in tumor tissue produced by polyoma virus-transformed cells.

2384 INDUCED CELLULAR DNA SYNTHESIS BY 'EARLY' AND 'LATE' TEMPERATURE-SENSITIVE MUTANTS OF POLYOMA VIRUS. (E.) Eckhart, W. (Salk Inst., San Diego, Calif.). *Proc Roy Soc Lond* 177(1046):59-63, 1971.

Mouse embryo fibroblasts were infected with 3 temperature-sensitive mutants of polyoma virus designated ts25, ts238 and ts697; these mutants were able to form plaques at 32° but not at 38°. Fibroblasts were infected at 32° and at 39°. Mutants ts25 and ts697 showed defective DNA synthesis at 39°; the virus yield for ts25 at 39° was 2.5×10^6 and for ts697 it was 5×10^6 ; for ts238, the virus yield at 39° was 1.5×10^7 . Mutants ts25 and ts697 were classified as "early" mutants and ts238 was classified as a "late" mutant. At 32°, ts25 and ts238 showed comparable virus yields and ts697 showed a markedly higher yield. When fibroblasts were infected with a wild-type polyoma virus it was found that the incorporation of ^3H thymidine into cells infected with virus was 2-5 times higher than in mock-infected cells. When fibroblasts were infected with temperature-sensitive polyoma mutants it was found that at 39° the mutants induced DNA synthesis (measured by uptake by infected cells of ^3H thymidine) in infected cells. It was emphasized that the mutants induced cellular DNA synthesis under temperature conditions in which viral gene products were deficient.

2385 PHENOTYPIC VARIATION AND ITS CONTROL IN POLYOMA-TRANSFORMED BHK21 CELLS. (E.)

Wyke, J. (Imperial Cancer Res. Fund, London, England). *Exp Cell Res* 66(1):209-223, 1971.

The 5-bromouracil + blue light selection method was applied to Methocel suspension cultures of polyoma-transformed clones, and variants of Py6/2 proved to be sufficiently stable to grow on soft agar with formation of flat colonies and with very little overlapping. These variants revealed that expression of phenotype in suspensions was reduced to a far greater degree than on a surface. Comparison of clone lines during the first 50 hr of culture showed approximately exponential growth with a mean doubling time of about 15 hr; 2 of the lines showed no sign of degeneration even after 300 hr in the same medium. "Re-transformed" segregants appeared slowly in one variant, but showed rapid appearance in another line. The variants comprised the bulk of the latter population within 30 generations.

2386 THE ANALYSIS OF MALIGNANCY BY CELL FUSION III. HYBRIDS BETWEEN DIPLOID FIBROBLASTS AND OTHER TUMOR CELLS. (E.) Wiener, F. (Karolinska Inst., Stockholm, Sweden), G. Klein and H. Harris. *J Cell Sci* 8(3):681-692, 1971.

Cells of a sarcoma induced by polyoma virus and a spontaneous carcinoma were fused with fibroblasts, mouse embryos and were assayed for tumorigenicity s.c. injection into syngeneic irradiated newborn mice (A.SW×CBA F₁) and allogeneic irradiated newborn mice. In the irradiated syngeneic recipients the wild type population and all clones with reduced chromosome numbers gave take incidences not far from 100%, but 3 of 5 clones that initially showed chromosome complement approximating the sum of the chromosomes of the two parent cells showed a greatly reduced cumulative take incidence. In all cases a range of chromosome numbers seen in the cells of tumors was very much broader than that to be expected from the fusion of one tumor cell with one fibroblast and in almost all cases there was a marked reduction in the modal chromosome number relative to that expected from the fusion. Evidence indicates that generation of malignant variants in the hybrid cell population requires not merely an overall reduction in chromosome number, but the elimination of some specific chromosome or chromosomes derived from non-malignant parent cell.

2387 TRANSFORMATION BY POLYOMA VIRUS AFFECTS ADHESION OF FIBROBLASTS. (E.) Edwards, J. G. (Dept. Cell Biol., U. Glasgow, Scotland), J. A. Campbell and J. F. Williams. *Nature* 231(22):147-148, 1971.

Suspensions of polyoma-transformed cells (Py) derived from clone 13 (C13) of a BHK21 fibroblast culture, unlike C13 cells, elicited decreased aggregation following minimal exposure to trypsin.

(200-300 BAEE U/ml for 3 min at room temperature) and EDTA. While aggregation of Cl3 cells persisted after 11 passages, Py cell lines showed decreased adhesiveness after 8 passages. Aggregation was scarcely detectable in growing Py lines. It is not known whether this decreased adhesiveness in the suspension system is shared by the interaction of the cells in culture and *in vivo*.

2388 SUSCEPTIBILITY TO SUPERINFECTION OF HYBRIDS BETWEEN POLYOMA "TRANSFORMED" BHK AND "NORMAL" 3T3 CELLS. (E.) Basilico, C. (New York U. Med Ctr., New York) and R. Wang. *Nature* 230(12):105-107, 1971.

Somatic hybrid lines were formed by plating C2F, a TK deficient derivative of the 3T3 mouse line which is fully permissive for polyoma multiplication, with one of 2 BHK Polyoma-transformed sublines T6Py5 or T6Py8 (both HGPRT deficient); hybrid cells were selected using medium containing aminopterin, thymidine and hypoxanthine. The transformed hybrids grew in soft agar, synthesized polyoma T antigen, had transformed phenotype morphologically, and exhibited the disordinate growth patterns of transformed cells. No infectious virus was shed by these hybrids nor was it possible to induce virus release by various treatments. All the hybrid lines produced virus when infected, although there was considerable variability in the yield. These experiments indicate that these hybrid cells possess no immunity to superinfection; the permissiveness of these cells to superinfection implies that polyoma-transformed BHK cells do not synthesize a dominant immunity substance with the characteristics of a diffusible viral repressor.

2389 THE ACTION OF POLYOMA VIRUS ON CELL PROLIFERATION *IN VITRO*. (Rus.) Makarova, G. F. N.F. Gamaleya Inst. Epidemiol. Microbiol. Acad. Med. Sci. U.S.S.R., Moscow) and I. S. Irlin. *Vop Virus* 6(1):16-20, 1971.

The mechanism of cell proliferation in polyoma virus-infected mouse and hamster embryo tissue cultures during various stages of growth was investigated *in vitro*. A marked decrease of the mitotic index (from 1.0 to 0.3) and of the labeled cell index (from 18 to 3) along with an increase of the duration of the mitotic cycle (from 20 to 28 hr) and an inhibition of DNA synthesis occurred during the logarithmic stage of growth in the mouse embryo tissue cultures 4 hr following infection. The infection of hamster embryo cells during the same state of growth led to a 10-fold increase of the mitotic index 3 hr following infection and to a stimulation of DNA synthesis. Contact-inhibited cell cultures of both mouse and hamster embryo cell cultures revealed enhanced mitotic indexes and stimulation of DNA synthesis. Parallel determinations of mitotic index and labeled cell index at short time incubation with labeled thymidine revealed the increase of the mitotic index to be preceded by 1 hr by an increase of DNA-producing cells. These results indicated that cells in stage G₂ were also stimulated by infection. Apparently polyoma virus

infection leads to a temporary loss of the contact inhibition control of the investigated cell cultures.

2390 EFFECT OF INTERFERON ON SOME ASPECTS OF TRANSFORMATION BY POLYOMA VIRUS. (E.) Taylor-Papadimitriou, J. (Imperial Cancer Res. Fund Lab., London, England) and M. Stoker. *Nature* 230(12):114-117, 1971.

Interferon inhibited polyoma virus-stimulated DNA synthesis in BHK cells in medium containing only 0.8% serum by 67%; this inhibition was not due to interferon blocking of stable transformation since only 0.03% of serum-deprived cells became stably transformed with the dose of virus used. Interferon had no inhibitory effect on serum-stimulated DNA synthesis. Formation of colonies of 8 cell equivalents or larger in methyl cellulose suspension cultures were inhibited 60-70% by exposure to interferon. The development of random orientation of transformed cells in monolayer cultures in conditions of serum depletion was also inhibited by interferon. The initial development of several characteristics of polyoma-transformed cells seemed to be inhibited by interferon irrespective of whether these characteristics were abortive or stably inherited, although no inhibitory effects were seen once stable transformation was achieved. Stable transformation was thought to involve integration, and an interferon-sensitive viral gene may be required for this event, or integration may modify viral gene products required for the expression of the transformed cell phenotype so that they become insensitive to interferon.

2391 ANTIGENIC HETEROGENEITY IN CELL POPULATIONS OF CLONED POLYOMA, VIRUS-INDUCED TUMOUR LINES. (E.) Negroni, G. (Imp. Cancer Res. Fund, London, England) and E. Hunter. *Nature* 230(9):18-20, 1971.

The variability in malignancy of cells derived from polyoma virus-induced tumors was investigated. Clones of transplantable fibrosarcoma and parotid tumors were derived from C₃H/Bi mice inoculated with polyoma virus. C₃H/Bi mice were immunized by 6 i.p. inoculations each of 1 x 10⁶ transformed non-malignant cells (line 7₂) twice/wk. Both immune and control mice were later inoculated s.c. with 10³-10⁶ malignant cells of fibrosarcoma (line 7₁) or of parotid tumor (line C₄d). The number of cells required to induce tumors in 50% of the preimmunized mice was 10-fold as compared to that required in the controls for both fibrosarcoma and parotid malignant lines. Quantitative comparison of the immune sensitivity of the malignant (7₁, C₄ and C₅) and non-malignant (7₂) cell lines was performed with trypsinized cells mixed with immune serum at 37°C for 1 hr and then with fresh guinea-pig complement for 45 min. The colony forming capacity of cells from this mixture was compared with that of identical cells mixed with normal serum and complement. Kidney cell cultures from 5 day old C₃H/Bi mice or embryo cell cultures from 14-day-old embryos of the same strain were used as controls. No considerable differences

between the number of colonies of control cells treated with normal serum and complement or immune serum and complement were observed. A 100% reduction in the number of colonies occurred when the immune serum (1:2) was mixed with no more than 1×10^5 non-malignant (7_2) cells. Titration of serum activity showed complete inhibition at a 1:16 dilution and a 50% inhibition at a dilution of 1:64 to 1:128. Complement fixing activity tests showed that 1×10^4 non-malignant cells (7_2) absorbed 1 U of complement at a serum dilution of 1:160; 5×10^4 cells of malignant lines 7_1 , C_4 and C_5 absorbed the same amount of complement at a serum dilution of 1:20; control cells (embryo) absorbed no complement. When the colony inhibition test was performed with more than 1×10^5 transformed non-malignant (7_2) cells certain amounts of cells survived the treatment with complement and specific immune serum. Two cell lines could be established *in vitro* from the surviving cell colonies. Cells from 1 of these colonies appeared to be immunosensitive and to produce slow growing tumors in mice. Cells from 3 malignant cell lines (parotid tumor, C_4d and C_5 lines, and fibrosarcoma, line 7_1) were only partially inhibited by specific immune serum and complement. Two subclones (A and B) were established from the 7_1 cell line. Cells of subclone A were not inhibited by specific immune serum and complement; cells of subclone B were moderately inhibited (20%).

- 401 ABSENCE OF ENHANCING ANTIBODY IN CELL
MEDIATED IMMUNITY TO TUMOR HETEROGRAFTS
IN PROTEIN DEFICIENT RATS. (E.) Jose, D. G. (Dept.
Med., Variety Club Heart Hosp., Minneapolis, Minn.)
and R. A. Good. *Nature* 231(5301):323-325, 1971.

The cellular and humoral immunity to DBA/2
mouse mastocytoma P-815-X2 ascites tumor
cells was studied in male Charles River rats
subjected to varying degrees of protein-
calorie deprivation which ranged from a low
of 8% casein to a control level of 30% casein.
The diets were started when the animals were
1 wk-old, and at 12 wk a single i.p. immunizing
dose of tumor cells was administered; spleen
cells and serum were obtained from one normal
immunized animal and from matched rats in the
different nutritional groups 11 days after
immunization. Spleen lymphocytes from immuni-
zed animals in all nutritional groups were
most equally active in mastocytoma target
cell lysis. Addition of inactivated serum
from sensitized animals on 30% protein diets
markedly inhibited cell mediated lysis in 7
experiments and showed less than 50% inhibi-
tion in 3 experiments. Serum from sensitized
protein deficient animals showed no inhibition
of cell mediated lysis in any of 10 experiments.
These results indicate that cell mediated immunity
can be maintained and specific antibody blocking
of cellular immunity or enhancing antibody can be
expressed in rats by feeding a diet of 8% casein.

- 402 STUDIES ON THE IMMUNOGENICITY OF PRENEO-
PLASTIC AND NEOPLASTIC MAMMARY TISSUES
IN BALB/c MICE FREE OF THE MAMMARY TUMOR VIRUS.
(E.) Weiss, D. W. (Dept. Immun., Hebrew U.-Hadassah
Med. Sch., Jerusalem, Israel), A. Sulitzeanu, L.
Kung, M. Adelberg and Y. Segev. *Israel J Med Sci*
7(1):187-201, 1971.

Highly inbred BALB/cCrg1 mice, free of mammary tumor
virus were given s.c. immunizing implants of 1 mm³
fragments of living tumor or living normal lactating
mammary tissue derived from an isogenic nursing
female or normal tail skin grafts taken from the
tumor donors, which were surgically removed when
tumors reached an approximate size of 5 x 5 mm or
after a period of 4 wk. Ten days later, sera were
collected by groups; the animals were challenged by
i.c. injection into the left inguinal region of a
freshly prepared suspension of viable tumor cells.
A pronounced increase in the incidence of progressive
tumors as a function of time resulted after challenge
in the tumor-immunized group. Repeat experiments,
using tumor tissue in the 9th transplant generation
compared to the 4th of the initial experiment,
revealed no significant differences in tumor inci-
dence between the differently pretreated groups; 50
to 75% of the mice developed cancers and the growth
rate in the tumor-and lactating mammary gland-
immunized groups was moderately enhanced. Animals
receiving pooled sera 6 hr before challenge with
tumor cells developed tumors somewhat later with a
slightly lowered incidence in the mice given serum
from the tumor bearers. Challenge of animals with

5 other types of tumor cells and heart-kidney frag-
ments (used as controls) revealed generally no
difference in the incidence of tumor development;
however, a time-related enhancement or repression
of tumor growth following challenge was seen after
immunization with pooled sera.

- 2403 BASIC PROTEINS AND SYNTHETIC POLYNUCLEOTIDES
AS MODIFIERS OF IMMUNOGENICITY OF SYNGENEIC
TUMOR CELLS. (E.) Braun, W. (Inst. Microbiol.,
Rutgers U., State U. New Jersey, New Brunswick), O.
J. Pleska, J. Raskova and D. Webb. *Israel J Med
Sci* 7(1):72-82, 1971.

Mice immunized with tumor cell homogenates or whole
tumor cells in conjunction with Freund's adjuvant
and pertussis vaccine were challenged with s.c.
injections of methylcholanthrene-induced sarcomas
or virus-induced ascites tumor cells. The incidence
of recurrence of excised tumors in vaccinated ani-
mals (4-27%) was consistently lower than that ob-
served in nonvaccinated animals (22-48%) for a
period from 7-39 days. The incidence of tumor
takes after challenge with the chemically-induced
tumor cell line revealed that the achievable pro-
tection was specific for the cell line employed for
immunization and did not extend to independently
derived tumor cell lines, including those induced
by the same carcinogen in the same inbred strain of
mice. Growth rate was lower in animals of the
tumor-excised, vaccinated group compared to animals
from the tumor-excised, nonvaccinated group. Treat-
ment with polyadenylic-polyuridylic acid after ex-
cision of syngeneic chemically-induced tumor cells
or at the time of implantation of virus-induced
cells decreased the frequency of recurrence or
rate of tumor growth.

- 2404 PROLIFERATION OF MACROPHAGE AND GRANULOCYTE
PRECURSORS IN RESPONSE TO PRIMARY AND TRANS-
PLANTED TUMORS. (E.) Hibberd, A. D. (Cancer Res. Unit,
Walter and Eliza Hall Inst., Melbourne, Australia) and
D. Metcalf. *Israel J Med Sci* 7(1):202-210, 1971.

The response of "in vitro colony-forming cells" (CFC)
to primary or transplanted syngeneic tumors and the
effect of tumor growth on colony-stimulating factor
(CSF) levels was studied in mice of strains AKR, BALB/c,
C3H, CBA, C57BL, 129/J and the F1 hybrids (NZB x
C57BL)F1 and (BALB/c x C57BL)F1. Almost all of the
AKR mice with spontaneous lymphoid leukemia exhibited
elevated levels of granulocyte and monocyte levels,
probably due to an increased production rather than a
prolonged intravascular life span of these cells.
The femur content of in vitro CFC was highly variable
in the leukemic mice, but 5 of 27 leukemic mice had
elevated levels and 14 of 27 had depressed levels of
in vitro CFC. Serum levels of CSF were elevated in
most leukemic mice, but there was no correlation
between serum CSF and either bone marrow content of
CFC or blood white cell levels. The incidence of in
vitro CFC was consistently elevated in the spleen of
mice bearing a variety of s.c. transplanted syngeneic
tumors at a stage when the tumor mass approximated
10-20% of body wt, compared to control animals; levels

of CSF and blood white cells were uniformly elevated in tumor-bearing animals. A detailed time study of the host response to HPC-28 and WEHI-10 tumors was made in BALB/c and C3H mice. When BALB/c tumor HPC-28 (H-2b) cells were injected into 129/J(H-2d), CBA(H-2k) and B10D2(H-2b) mice, no detectable tumor growth occurred in any of the recipients, although there was a rise in *in vitro* CFC. HPC-28 and WEHI-10 were found to contain low levels of CSF and the contents did not change significantly with progressive enlargement of the tumors.

- 2405 EXPERIMENTAL MODELS FOR EVALUATION OF HOST DEFENSES IN CANCER. (E.) Stern, K. (Dept. Life Sci., Bar Ilan U., Ramat Gan, Israel) and A. Goldfeder. *Israel J Med Sci* 7(1):42-51, 1971.

Immune responses to sheep RBC were determined at 5, 10 and 14 days after immunization in mice of strains X/Gf, IBA, C57BL/S and C3H/S that had been subjected to total body X-irradiation of 300 R 4, 7 and 12 days previously; reticuloendothelial cell phagocytosis of ^{51}Cr -labeled sheep RBC was assayed in tumor-free and tumor-bearing (injected s.c. with syngeneic mammary tumor cells) mice. Significantly lower levels of antibodies (from agglutinin and hemolysin values) were found in all groups of irradiated mice compared to controls regardless of strain and timing of immunization. At the termination of the experiments on day 14, X/Gf mice immunized 4 and 7 days after irradiation exhibited 18-60% greater spleen weights than control animals; the increase was paralleled by the presence of increased lymphoid tissue. In reticuloendothelial cell phagocytosis assays, significant impairment of splenic phagocytosis occurred in all tumor-bearing C3H/S mice but not in X/Gf mice. Splenomegaly was more pronounced in tumor-bearing X/Gf than in C3H/S animals. Hepatomegaly was seen in tumor-bearing mice of both strains, but hepatic phagocytosis was not significantly affected by X-irradiation.

- 2406 RECOGNITION OF LEUKAEMIA CELLS AS FOREIGN BEFORE AND AFTER AUTOIMMUNIZATION. (E.) Powles, R. L. (Chester Beatty Res. Inst., Surrey, England), L. A. Balchin, G. H. Fairley and P. Alexander. *Brit Med J* 1(5747):486-489, 1971.

The reactivity *in vitro* of leukemic lymphocytes against autologous leukemic cells following autoimmunization was investigated. Leukemia cells in the peripheral blood of 9 patients with acute leukemia were collected and stored with dimethylsulfoxide (DMSO) in tissue culture medium 199 at -179°C . Lymphocytes from peripheral blood of the same patients in remission were cultured with the thawed autologous leukemia cells. Autoimmunization was achieved with stored leukemia cells subjected to irradiation (at 4°C at a concentration of 10^8 cells/ml with a dose of 10,000 rads using ^{60}Co γ -irradiation at 1,500 r per min); the cells were injected within 30 min into all 4 limbs both intradermally and s.c. Stimulation of remission lymphocytes by stored autologous leukemia cells occurred in all 9 patients.

Autoimmunization led to increased stimulation of patient lymphocytes within a few days; it also affected their capacity to respond to normal allogeneic cells. Those cases where allogeneic stimulation was below the normal range before autoimmunization showed an increase in their response, and cyte recognition of leukemic cells was more pronounced than recognition of allogeneic cells. The lymphocytes seemed to have responded in both a specific and a non-specific manner following autoimmunization. It was not possible to determine, under the experimental conditions used, whether the antigen(s) in human acute leukemia is individually specific or chemically-induced animal tumors or "group" specific as in the neoantigens of virus-induced tumors, or the cause of interference by transplantation antigens.

- 2407 COEXISTENCE OF INTRASPECIES AND INTERSPECIES SPECIFIC ANTIGENIC DETERMINANTS ON THE MAJOR STRUCTURAL POLYPEPTIDE OF MAMMALIAN C-TYPE VIRUSES. (E.) Gilden, R. V. (Flow Lab. Inc., Rockville, Md.), S. Oroszlan and R. J. Huebner. *Nature* 231(21):107-108, 1971.

Gel diffusion assays using various selected sera against mouse, hamster and cat crude and purified C-type viral antigens indicated that the cross-reactive antigenic determinants were specifically located on the major structural polypeptides of C-type viruses. When analyzed in SDS-acrylamide gel electrophoresis, mouse (MuLV), hamster (HaLV) and cat (FeLV) C-viruses disrupted by SDS, urea and mercaptoethanol were shown to possess 3 distinct major polypeptide components. The slowest migrating of these components (molecular wt 26,000-35,000) clearly carried the major group-specific determinants (gs-1) common to C-type viruses. These group-specific antisera showed a high degree of specificity for their homologous viruses in both complement-fixation and gel diffusion assays. However, sera from a few rats bearing murine sarcoma virus-induced transplant tumors, from rats immunized with homogenates of such tumors (MSV-I-1) reacted strongly with both HaLV and infected cells and purified virus after ether extraction. MSV-I-1 and guinea pig anti-MuLV-gs-1 reacted with both disrupted virus pellets and purified MuLV to give lines of identity; MSV-I-1 4 times gave 2 bands with the slow moving peptide component. Partial identity reactions were observed between the slow moving component and MuLV, HaLV and FeLV, suggesting that both species specific determinants and interspecific determinants reside on the same molecule. Absorption tests, heat inactivation kinetics and cross reactivity tests confirmed these results.

- 2408 RESISTANCE AND SUSCEPTIBILITY TO TRANSFERRING VI. REACTION OF LABELLED LYMPHOID CELLS TRANSFERRED INTO THE SITE OF PREVIOUSLY IMPLANTED CARCINOMA. (E.) Dvorak, R. (Dept. Path., U. Hamburg, Germany) and J. Lindner. *Neoplasma* 18(1):63-86, 1971.

Strain BALB/c and CBA/j mice were pretreated with Endoxan prior to receiving transplanted Bo4 cells.

oma or Ehrlich ascites carcinoma cells in the upper lip; 5 hr after tumor transplantation, mice were given injections of ^3H -thymidine-labeled lymphoid cells from syngeneic animals. Isolated lymphoid cells were from the lymph nodes, spleen or thymus of donor mice; in some cases the lymphoid cell donors had been immunized with living tumor cells. Following injection of the labeled lymphoid cells to the region of the tumor transplant, the lymphoid cells disintegrated; thymic cells disintegrated more quickly after injection than did splenic cells or lymph node cells. Of lymphoid cells found in the tumor region, lymphocytes and "differentiated blast cells" were markedly more abundant than fibroblasts, polynuclear leukocytes, or other mesenchymal cells. Preimmunization of lymphoid cell donors accelerated the rate of disintegration of injected spleen and lymphoid cells in the tumor-bearing hosts. In all mice implanted with the Bo4 carcinoma, some round-nucleated lymphocytes and spleen cells transformed themselves into fibroblasts and other mesenchymal cells composing the periblastomatous connective tissue and tumor mass.

DETECTION OF ANTIGENIC SUBUNITS OF A MURINE LEUKEMIA VIRUS BY PASSIVE HEMAGGLUTINATION-INHIBITION. (E.) Sibal, L. R. (Nat'l. Cancer Inst., Nat'l. Inst. Hlth., Bethesda, Md.), V. W. Anderson, Jr. and M. A. Fink. *J Immunol* 106(4):1050-1055, 1971.

Passive hemagglutination test modifications which identify clearly the viral antigen-antibody reactions for study and methods of separation of such viral antigens are presented. The purified Rauscher leukemia virus (RLV) used to sensitize tanned sheep erythrocytes was the 1.16 g/ml isolate of supernatant fluid from infected tissue cultures. Antiserum to RLV was prepared in Rhesus monkeys and BALB/c mice by standard methods. Tween 80-ether treatment of purified RLV released 2 antigenic subunits which could be separated into highly purified subunits by density gradient centrifugation and column chromatography. One of these was identified as a group-specific antigen as seen from the reaction between tanned sheep erythrocytes coated with ether-treated virus and mouse antiserum. The other was identified to be an envelope antigen of the virion; its inhibition of the reaction between tanned sheep erythrocytes coated with tween-ether- or deoxycholate-treated virus and mouse antiserum free of anti-group-specific antigen indicated it to be a group-specific antigen of the virus. Antiserum to RLV produced in monkeys agglutinated tanned sheep erythrocytes coated with both antigens, while BALB/c antiserum reacted only with the envelope antigen. The usefulness of the passive hemagglutination-inhibition reaction for the independent assay for each of these antigens is emphasized.

IMMUNOLOGICAL STUDIES ON MOUSE MAMMARY TUMORS AND LEUKEMIA. (E.) Dmochowski, L. (Texas M.D. Anderson Hosp. Tumor Inst., Houston),

W. C. Williams, G. R. Swearingen, B. Myers and S. Fujinaga. *Texas Rep Biol Med* 29(1):41-62, 1971.

Intravenous inoculation of New Zealand white rabbits with mouse mammary tumor virus (MTV) from milk of RIII/Dm and of A/Dm high-mammary-cancer strain mice produced immune sera that appeared to be specific for the whole MTV virion. One of the precipitate lines produced by the anti-MTV sera against MTV antigens from milk of these 2 strains contained characteristic type B (or MTV) particles. This precipitate line was not removable by absorption with tissue preparations from low-mammary-cancer strain mice; its appearance was found to be prevented upon testing of the immune sera against milk of mice with low incidence of mammary cancer (BALB/C/Dm or C57BL/6/Dm). Immunodiffusion tests revealed a similarity of the MTV from different strains of mice. The anti-MTV serum gave a positive mixed hemadsorption reaction (MHA) with both spontaneous and induced mouse mammary tumors containing MTV (type B particles) and/or MLV (type C particles). A negative MHA reaction occurred with a cell line derived from an induced mammary tumor in a BALB/c/Dm strain mouse where no type B or type C virus particles could be found by electron microscopy. Positive MHA reactions with the anti-MTV serum were obtained with cultures of leukemic tissues, of mouse embryos and of a 3-methylcholanthrene-induced mouse sarcoma, all shown to contain type C particles. The MHA reaction of the investigated anti-MTV serum appeared to be specific for both MTV and MLV. Positive MHA reactions were given also by an anti-MLV serum with cultures of leukemic tissues, mouse mammary tumors and mouse embryo tissues containing type C particles; this reaction appeared to be due to the presence of antibodies to heterophile and viral antigens in MLV infected tissues. The positive MHA reaction given by anti-MTV and anti-MLV sera with tissues containing both type B and type C particles indicates the presence of antibodies to type C particles in the investigated anti-MTV sera and the widespread presence of MLV.

2411 AN APPROACH TO THE IMMUNOLOGICAL REGRESSION OF THE TUMOR. (E.) Kobayashi, H. (Hokkaido U. School of Med., Sapporo, Japan). *Acta Path Jap* 20(4):441-450, 1970.

Immunological features of Friend virus-induced tumors in Wistar King Aptekman/Mk rats are reviewed. Inoculation of Friend virus in newborn rats produces leukemia or lymphosarcoma within 5-7 months; these neoplasms are referred to as rat Friend tumors (RFT). RFT do not grow well in adult isologous strain rats, their growth occurs only in Friend virus-tolerant or immunologically immature rats, in which the primary target organs appear to be the spleen and the thymus. Cytotoxic tests and electric charge studies showed that the growth patterns of the RFT tumors are closely related to the cell membrane surface properties. The chromosome pattern of the RFT appears to present fewer anomalies than other neoplasms. The poor transplantability characteristics in isologous rats seem to be due to a membrane antigen originating from the Friend virus.

which is associated with the transplantation antigen, referred to as virus-specific transplantation antigen (VSTA). Reference is made to certain neoplastic cell cultures which under certain conditions of *in vitro* cultivation (i.e., exposure to 4-nitroquinoline-N-oxide) lose their oncogenicity upon inoculation into experimental animals; this phenomenon is referred to as disdifferentiation and may be due to a mutation of the tumor cell. (16 references)

- 2412 HOST RESPONSE IN SPONTANEOUS REGRESSION OF MURINE LEUKEMIA. (E.) Rich, M. A. (Albert Einstein Med. Ctr., Philadelphia, Pa.) and R. Clymer. *Cancer Res* 31(6):803-807, 1971.

Serum from strain Swiss ICR/Ha mice that had been inoculated with a strain of Friend leukemia virus, which gives rise to spontaneously regressing leukemia, was injected into mice; in the donor mice leukemia had appeared and regressed following inoculation of the virus. The capacity of sera to confer immunity to Friend leukemia virus was tested. Leukemia developed in 1 of 9 infected mice given serum from mice bearing regressed leukemias, while in infected mice given serum from normal mice and from leukemic mice, leukemia developed in 8 of 9 and 9 of 10 mice, resp. Infection and leukemia development did not induce resistance to reinfection with Friend leukemia virus. Whereas mice inoculated with the strain of Friend virus which gave rise to regressing tumors showed a high incidence of leukemia regression, mice inoculated with both the regressing strain of virus and with a strain of Friend virus which produced persistent leukemia developed leukemia which did not regress.

- 2413 FELINE LEUKAEMIA VIRAL ANTIGENS AND ANTISERA TO THE GROUP SPECIFIC ANTIGENS OF THE MURINE LEUKAEMIA VIRUSES. (E.) Sarma, P. S. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), R. J. Huebner, H. C. Turner, R. V. Gilden and T.-S. Log. *Nature* 230(10):50-52, 1971.

The interspecies immunological reaction between the murine and feline C-type viruses has been applied to the quantitative study of the feline leukemia viruses (FuLV). Murine sarcoma virus (MSV) rat serum pools were prepared by mixing Fischer rat sera carrying transplanted syngeneic sarcomas induced by the Moloney strain of MSV. Pool 20 was prepared from sera which gave complement fixation antibody titers greater than 1:80 against Murine leukemia virus (MuLV) tissue culture viral antigens and MSV rat tumor antigens. The broad reacting pool 21 was prepared in the same manner, except that it included several rat sera which also reacted with antigen preparations of murine tissues containing the C-type viral genome that had no infectious features such as non-producer MSV rat tumors. The feline leukemia and sarcoma group specific antiserum used in complement fixation assays of feline C-type viruses was prepared in a beagle by the induction of a fibrosarcoma with the GA strain of feline sarcoma virus (GA-FSV). The tissue culture complement

fixation antigen induction test for FeLV and FSV was performed by inoculation of the virus into feline embryo fibroblast (FEF) monolayer culture and by determination of the subsequent occurrence of the viral group specific antigens in these cultures. MSV rat serum pools 20 and 21 reacted in complement fixation tests with feline virus specimens such as purified virus preparations, clarified 20% extracts of feline lymphosarcoma and cell culture antigens of FEF infected with the FeLV and FSV. Titres obtained with MSV pool 20 were lower than those revealed by MSV rat serum pool 21, which were identical to those given by the feline group specific antiserum prepared in a beagle. The group of the noncytopathogenic FeLV in FEF cultures was readily detected by complement fixation tests with the broad reacting MSV pool 21. The usefulness and sensitivity of the broad reacting MSV pool 21 for detection of FeLV is emphasized after comparison with results obtained by other techniques.

- 2414 STUDIES ON THE LOCALIZATION OF RADIOLABELLED ANTIBODIES TO A MOUSE MYELOMA PROTEIN. (E.) Reif, A. E. (Dept. Surgery, Tufts Med. Sch., Boston, Mass.). *Cancer* 27(6):1433-1439, 1971.

Cell suspensions of plasma cell tumor fragments incubated with ^{125}I -antibody and normal ^{131}I - γ -globulin for 30 min were injected s.c. into young adult BALB/c female mice. All mice injected with 50,000 or more cells died with tumors and those injected with 5,000 or fewer cells survived permanently without evidence of tumor growth at any time. In tumor cells incubated with paired-labeled antibody, the addition of increased amounts of the mixture resulted in the binding of an increased proportion of antibody. *In vivo* results of paired-labeled antibody injections revealed that injection of unlabeled whole antiserum to protein M 3 hr prior to the paired-labeled mixture appeared to reduce the proportion of antibody relative to normal γ -globulin that remained present in blood, muscle, kidney and tumor tissue. Radiolabeled antibody injections revealed the rate of excretion to be estimated at 42% per day, while that of normal γ -globulin was only 24% per day. Localization of antibody in tumor was obtained only in 1 group of mice in which the localization index relative to kidney was 13.1, 5.9 and 6.8, resp., and relative to muscle was 5.7, 1.86, and 2.0 resp., giving an average of 8.6 fold increase in localization of antibody in tumor over kidney and a 3.2 increase over muscle.

- 2415 ANTIBODY AGAINST NEOPLASTIC PLASMA CELLS. I. SPECIFIC SURFACE ANTIGENS ON MOUSE MYELOMA CELLS. (E.) Watanabe, T. (Roswell Park Memorial Inst., Buffalo, N. Y.), Y. Yagi and D. Pressman. *J Immunol* 106(5):1213-1221, 1971.

Surface antigens were found on strain BALB/c mouse myelomas which were not present on lymphocytes, liver and kidney cells. Rabbit antisera were raised against cellular components of mouse myelomas and

against lymph node cells. Cells of 6 myeloma lines were used in immunization and fluorochromasia cytotoxicity tests. Sera cytotoxic to all the myeloma lines were obtained which were not cytotoxic to normal lymph node cells. Absorption with myeloma sediments readily removed the myeloma-cytotoxic antibodies from the sera; however, sediments from thymus liver and kidney failed to remove the myeloma-cytotoxic antibodies. Antisera which were cytotoxic to 1 of the myeloma lines were cytotoxic to the other lines; no antigens specific to any 1 line were detected. While lymphocyte-cytotoxic antisera were developed which yielded lymphocyte-cytotoxic antibodies when treated with lymph node, spleen or thymus sediments, sediments of myeloma cells and of liver and kidney cells were not effective in removing antibodies from lymphocyte-cytotoxic sera.

16 EVOLUTION OF CELL-MEDIATED IMMUNITY IN MICE BEARING TUMORS PRODUCED BY A MAMMARY CARCINOMA CELL LINE. INFLUENCE OF TUMOR GROWTH, SURGICAL REMOVAL, AND TREATMENT WITH IRRADIATED TUMOR CELLS. (E.) Le Francois, D. (Gustave-Roussy Inst.), K. Youn, J. Belehradsky, Jr. and G. Barski. *J Nat Cancer Inst* 46(5):981-986, 1971.

Bred adult female mice of the mammary tumor virus-free C3HeB/Fe strain were inoculated s.c. with a cell line (TMI) from a spontaneous mammary tumor of C3H mouse, and peritoneal cells obtained from washings of the peritoneal cavity following tumor formation were used to test TMI colony growth inhibition *in vitro*. Inhibition approximated 64-100%; the peritoneal cells demonstrated specificity by their inability to suppress colony growth of other, unrelated homologous tumor cells. Between the 7th and 9th day after inoculation of the initial tumor cells in 3 experiments, the peritoneal cell inhibition was 21% and in all cases, 16 days or later when the tumor size was 7 mm or more in diameter, peritoneal cells entirely lost their inhibitory capacity; peritoneal cells from animals bearing huge tumors seemed to have an enhancing effect on cell growth. Surgical removal of the tumors 35-40 days after inoculation of TMI resulted in a return of specific cell immunity in peritoneal cells spontaneously and reached high levels by the 23rd day after surgery. Peritoneal cells from animals receiving trypsinized irradiated tumor cells from the excised tumor on the 1st postoperative day showed a 59% inhibitory activity on day 10 compared to 24% activity in cells from the control group and lack of reactivity in cells from a group of animals receiving homologous spleen cells following surgical removal of the tumor. The role of lymphocytes and macrophages in inhibiting target cell colony growth *in vitro* is unclear.

17 NATURAL ANTIBODIES IN NORMAL HUMAN SERA AGAINST THE EHRlich MOUSE ASCITES TUMOUR IDENTIFIED WITH THE AID OF COMPLEMENT COMPONENTS, UTILIZING CLASSICAL REAGENTS. (E.) Oravec, C. Cancer Res. Inst., Slovak Academy of Sciences,

Bratislava, Czechoslovakia) and J. Cambelova. *Neoplasma* 18(2):141-159, 1971.

Undiluted and/or diluted (up to 1:8) sera from 93 samples of venous blood from 20 clinically healthy donors were incubated with Ehrlich mouse ascites tumor cells; these samples and the same sera without tumor cells (controls) were examined for complement levels before and after absorption with tumor cells. Values before absorption in undiluted samples ranged from 75.75-157.44 U/ml and after absorption from 0.70-94.512 U/ml, a decrease of 17%-99%. Dilutions of sera in a 1:2 and 1:4 ratio resulted in a diminution of complement in absorbed fractions which were statistically significant, but dilutions after the original sera had been freed from complement by absorption did not show any diminution in values. The cytotoxic activity of natural antibodies in normal human sera against the tumor cells was not markedly affected by application of heat at 56°C for 20 min and in one instance was stimulated when cells were suspended in a veronal buffer. However, complement levels and viable cell titrations did not show any correlation.

2418 TUMOR-DISTINCTIVE CELLULAR IMMUNITY TO HUMAN SARCOMA AND CARCINOMA. (E.) Vanky, F. (Karolinska Inst., Stockholm, Sweden) and J. Stjernswärd. *Israel J Med Sci* 7(1):211-220, 1971.

Lymphocytes obtained from the peripheral venous blood of 20 cancer patients preoperatively were mixed with autochthonous tumor tissue cells in which DNA synthesis had been blocked by mitomycin-C and incubated at 37°C for 5 days followed by the addition of ³H-thymidine for 12 hr. The lymphocytes were stimulated to increased DNA synthesis by the autochthonous tumor cells in 11 patients with an index above 1.5. The lymphocytes from these 11 patients were stimulated by allogeneic cells with a reactivity index of 2.5-10.3. DNA synthesis in allogeneic effector lymphocytes from a healthy donor was stimulated to a greater extent (>2-fold) by the lymphocytes than by tumor cells taken from the same patient. Autochthonous lymphocytes were stimulated more frequently (7 of 12) by the tumor cells than were the allogeneic lymphocytes (4 of 12). Sarcoma cells stimulated allogeneic lymphocytes less frequently than did carcinoma cells. These *in vitro* tumor-distinctive cellular immune reactions were also observed between autochthonous frozen and thawed tumor cells and lymphocytes and between lymph node cells draining the tumor and autochthonous lymphocytes.

2419 SERUM CONCENTRATIONS OF γ G, γ A AND γ M IMMUNOGLOBULINS IN PATIENTS WITH CARCINOMA, MELANOMA, AND SARCOMA. (E.) Hughes, N. R. (Prince of Wales Hosp., Randwick, Australia). *J Nat Cancer Inst* 46(5):1015-1027, 1971.

Sera from 256 normal controls and 984 patients with carcinoma of nonhematopoietic tissue were analyzed for concentrations of γ G, γ A and γ M immunoglobulins by means of ammonium sulfate fractionation and

chromatographic techniques. Male patients with carcinoma of the skin or ulcerative colitis and male and female patients with lung cancer had mean γG concentrations significantly increased above normal. Male controls as well as male patients with all cancers had significantly higher γA concentrations; significantly higher mean concentrations of γA were observed among male patients with carcinoma of the skin, colon and rectum ($0.01 > P > 0.001$), and lung ($0.02 > P > 0.01$). For females, higher than normal γA concentrations were found in patients with carcinoma of the mouth, colon, rectum, and uterus. Female controls had a significantly higher mean γM concentration than male controls ($0.001 > P$). Female patients with melanoma had a significantly higher mean γM concentration than male patients with melanoma ($0.001 > P$). Male patients with sarcoma and female patients with melanoma had a mean γM concentration significantly higher than normal, while patients with primary cancer of the ovary had a γM mean concentration significantly lower than normal. Normal males had a significantly higher mean $\gamma A/\gamma G$ ratio than normal females ($0.001 > P$). A significantly higher mean ratio of $\gamma A/\gamma G$ in males than in females was also found for patients with cancers of the lung ($0.01 > P > 0.001$), mouth ($0.05 > P > 0.02$), colon and rectum ($0.001 > P$), and cancers of the mouth and gut combined ($0.001 > P$); in males the mean $\gamma A/\gamma G$ ratio was significantly increased above that of normal controls in patients with cancer of the mouth, stomach, duodenum, colon and rectum. For females, this ratio was significantly increased above controls in patients with cancer of the mouth, colon and rectum, and uterus.

- 2420 ANTIGENICITY OF TWO ESTABLISHED TUMORIGENIC CELL LINES ESTIMATED BY THE MIGRATION INHIBITION TEST. (E.) Kieler, J. (Fibiger Lab., Kgs. Lyngby, Copenhagen, Denmark) and K. Ostrowski. *Proc Soc Exp Biol Med* 137(1):130-134, 1971.

Inbred strains of C₃H and DBA/2 mice were immunized by s.c. injection of two sarcoma tumor cell lines (L-1 and L-2c) and reimmunized after 1-6 wk; the immunological response was challenged *in vivo* by the s.c. transplantation of 0.2 ml of minced C₃H-L1 and C₃H-L2c tumor tissue and *in vitro* by the migration inhibition test. The low incidence of mice with progressively growing tumors following preimmunization (0-18%) with L-1 and L-2c cells and challenge with *in vivo* propagated C₃H-L1 tumor indicated that common isoimmunizing antigens were present in the 2 cultured cell lines and the C₃H-L1 tumor. An absence of similar protection against the C₃H-L2c tumor suggested that this tumor did not share these antigens. However, cross-reaction between the cultured L-2c cells and the C₃H-L2c tumor was demonstrated by the migration inhibition test *in vitro*; the negative result of the transplantation test in immunized mice was interpreted as a manifestation of the high virulence of the C₃H-L2c tumor.

- 2421 INDUCTION OF LONG TERM LYMPHOCYTE LINES FROM DELAYED HYPERSENSITIVE HUMAN DONORS USING SPECIFIC ANTIGEN PLUS EPSTEIN-BARR VIRUS. (E.)

Baumal, R. (Albert Einstein Coll. Med., Bronx, N. Y.) B. Bloom and M. D. Scharff. *Nature* 230(9):20-21, 1971.

Peripheral white cells from delayed hypersensitive subjects were used to establish selective antigen sensitive cells in culture by combined exposure to specific antigen and Epstein-Barr virus (EBV) *in vitro*. Venous blood was collected from healthy donors with delayed skin reactions either to tuberculin (PPD 0.0001 mg) or to streptokinase-streptodornase (SKSD 10 U). Aliquots of white cell suspension containing 8×10^6 cells/ml in culture medium were incubated in the presence or absence of 5 μ g of PPD or 50 μ g/ml of SKSD. The cells were then treated with EBV (incubation at 37°C for 1 hr). Controls included cells which received antigen but not EBV, cells which received EBV but no antigen and cells which received neither EBV nor antigen. Cell growth was observed 6 wk after initiation of the cultures. Continuous lines were established only from cells treated with the combination of EBV and antigen to which the donor was sensitive (according to the skin reactivity to PPD or SKSD). These cultures continued to produce a variety of fully or partially assembled immunoglobulin molecules constituting 5-30% of the newly synthesized cytoplasmic proteins. No evidence was found whether these cells were antigen sensitive or whether they were producing specific antibodies. Untreated or antigen alone-treated cells failed to grow. When treated with virus alone, cells showed transient growth with no further propagation.

- 2422 AN INHERITED MURINE SERUM COMPONENT RELATED TO MAMMARY CANCER. (E.) Berrington, P. (Bio-Res. Inst., Cambridge, Mass.), R. E. Berrington and C. H. Yoon. *Proc Soc Exp Biol Med* 137(1):5-1971.

A murine serum trace component (SMT-antigen) was found to be a genetically determined characteristic transmissible by either sex. Reciprocal crosses made between C₃H/HeJ mice (of which 90% of the females are positive for SMT-antigen) and BALB/c mice (of which none of the virgin females show positive SMT-antigen reactions). F₁ mice were crossed to F₁ littermates and backcrossed to either parent strain. Although only females exhibit the serum antigen, both reciprocal crosses produced serum positive females with nearly equal frequencies. Every type of backcross to BALB/cJ parents produced certain proportions of SMT-antigen-positive females. Involvement of an infectious factor was ruled out by breeding BALB/cJ females first with C₃H/HeJ males, then BALB/cJ males; no SMT-antigen was found in offspring of the latter mating. Foster-nursing experiments eliminated the possibility of milk transmission of an infectious agent. The distribution of SMT-antigen-positive and -negative F₂ hybrids and backcross offspring indicated the presence of a pair of modifier genes, which prevent the expression of major SMT-antigen genes when present in a recessive homozygous condition. This SMT-antigen component may represent the genetic factor involved in the formation of spontaneous mammary tumors in mice.

3 ANOMALOUS ANTIGENS IN EXPERIMENTAL HEPATOCARCINOGENESIS. (Rus.) Khundanova, L. L. N. Petrov Res. Inst. Oncol. U.S.S.R. Ministry of Health, Leningrad). *Vop Onkol* 17(3):85-90, 1971.

une sera against liver or hepatoma antigens of s receiving 10 mg dimethylaminoazobenzene (DAB) ly p.o. for 300 days were obtained 4, 15, 30, 60, and 400 days after the beginning of carcinogen inistration. Double gel diffusion, immunoelectro-esis and complement fixation reactions indicated t 4 specific anomalous antigens were formed during hepatocarcinogenic process. Immunoelectrophoretic ility showed that anomalous antigen I occurring ly at 4-30 days was within the α -globulin zone; gen II detected in the albumin and α -globulin e and antigen III in the β - and γ -globulin zone rred within 30, 60 and 100 days of the process. gen IV which was isolated from hepatomas and h migrated to the albumin and α -globulin region detected at 400 days of hepatocarcinogenesis. of the 4 anomalous antigens (I and IV) were d to be organ specific for liver cells and it assumed that all 4 types of antigens participate the DAB-induced hepatocarcinogenesis.

EVIDENCE FOR IMMUNOLOGICAL SURVEILLANCE DURING SKIN CARCINOGENESIS: INFLAMMATORY IN IMMUNOLOGICALLY COMPETENT MICE. (E.) Lappe, Cancer Res. Genet. Lab., U. California, Berkeley). *Israel J Med Sci* 7(1):52-65, 1971.

microscopic features of skin tumor formation and ination were studied in isografts of 3-methyl-anthrene-treated skin transplanted to female /cCrgl mice with varying degrees of immunologic etence; the latter was achieved by pretreatment BCG(MER) or saline injections, sublethal whole-X-irradiation (450 R), or antilymphocyte serum) injections. Three to 4 grafts were examined each group 9-39 days after grafting. Micro-ic papillomas were commonly seen in sections n from grafts transplanted 2-4 wk after grafting. he 3rd wk after grafting, papillomas were rved in about 20% of the hosts which had received er X-irradiation or ALS treatment, but macroscopic llomas were not seen in immunologically competent s till after the 4th wk postgrafting. Focal s of intense lymphocytic infiltration were found ng the latent period of papilloma development in etent but not in depressed hosts. The presence lymphocyte exocytosis in conjunction with dermal tin debris from former epithelial pearls were d in MER-stimulated hosts 25-39 days after graft- these sites may represent the residue of for-microscopic papillomas. The total number of oscopic and macroscopic papillomas recorded in etent hosts was 25 out of a total of 62 grafts ared to 34 papillomas in the 56 grafts made to essed hosts. When inflammatory foci are included the tabulation of papilloma group totals, there actually comparable numbers of lesions in the etent and depressed groups. This observation is istent with the possibility that in competent s a portion of the incipient papillomas were

destroyed at a microscopic level and were later scored as inflammatory foci, as predicted by the theory of immunological surveillance.

2425 EFFECT OF IMMUNE STATUS ON THE DEVELOPMENT OF ARTIFICIALLY INDUCED METASTASES IN DIFFERENT ANATOMICAL LOCATIONS. (E.) Vaage, J. (U. Texas M.D. Anderson Hosp. Tumor Inst. Houston), K. Chen and S. Merrick. *Cancer Res* 31(5):496-500, 1971.

Twelve-wk-old male mice of an inbred strain C3Hf/Bu were challenged with fibrosarcoma cells 1 day after destruction by irradiation or surgical removal of 18-day-old sensitizing fibrosarcoma implants. Controls without presensitizing implants and animals given sublethal whole-body irradiation 1 day before challenge were also challenged with fibrosarcoma cells. The mice that had been cured of their sensitizing tumor implants had acquired a high degree of resistance to challenge; booster injections of killed tumor cells on days 7 and 14 after challenge enhanced the resistance and only 0-33% of the animals developed tumors compared to a 5-52% tumor incidence in presensitized animals without booster, a 50-95% tumor incidence in controls and a 75-100% tumor incidence among those receiving irradiation.

2426 TUMOR-SPECIFIC ANTIGENS IN 2-ACETYLAMINO-FLUORENE-INDUCED RAT HEPATOMAS AND RELATED TUMORS. (E.) Baldwin, R. W. (British Empire Cancer Campaign Res. Labs., U. Nottingham, England) and M. J. Embleton. *Israel J Med Sci* 7(1):144-153, 1971.

Wistar rats of both sexes treated with 0.04% dietary 2-acetylaminofluorene (AAF) or 0.006% diethylnitrosamine (DENA) developed hepatocellular carcinomas, ear duct squamous cell carcinomas and nephroblastomas. AAF- and DENA-induced tumor cell preparations were used to immunize other rats against subsequent tumor cell challenge; in some cases, immunizing tumor cells were exposed to ^{60}Co γ -irradiation prior to injection into rats. Tumor-specific transplantation antigens were detected in 3 of the 9 AAF-induced hepatomas by the capacity of irradiated (15,000 r) immunizing grafts to induce resistance against challenge. AAF-induced hepatomas were only weakly immunogenic; immunized rats only rejected challenges with low numbers of tumor cells. Immunizing inocula which conferred immunity against a challenge with 10^4 tumor cells failed to immunize against 2×10^4 tumor cells. The low immunogenicity of AAF-induced liver tumors was further demonstrated by their inability to induce reproducible tumor-specific humoral antibody reactions detectable by membrane immunofluorescence tests. Resistance to challenge inocula of $1-2 \times 10^5$ cells of the immunizing tumor was seen following immunization with DENA-induced hepatomas. Resistance to challenge with ear-duct carcinomas induced by AAF was seen in all but 1 mouse challenged with 5×10^4 ear-duct carcinoma cells; however, this resistance broke down a subsequent challenge with 10^5 tumor cells. No resistance was seen against nephroblastomas.

- 2427 THE INFLUENCE OF CARCINOGENIC NITROSAMINES ON THE INDUCTION OF SERINE DEHYDRATASE IN THE RAT LIVER. (Ger.) Jennissen, H. (Biochem. Inst., U. Freiburg, Germany), J. Hoshino and H. Kröger. *Z Krebsforsch* 75(4):246-252, 1971.

Sprague-Dawley rats were given N-nitrosomorpholine (10 mg/kg) or diethylnitrosamine (4 mg/kg) in drinking water daily, and the effects of these agents on the induction of serine dehydratase by casein hydrolysate and by fasting were observed. Neither carcinogen affected the induction of serine dehydratase by casein; however, the induction of the enzyme by fasting was potentiated by diethylnitrosamine. N-nitrosomorpholine did not affect fasting induction of serine dehydratase. An increase in enzyme synthesis was thought to be the cause of the increased activity induced by fasting.

- 2428 TRANSFER OF IMMUNITY TO TUMOUR ISOGRAFTS BY THE SYSTEMIC ADMINISTRATION OF XENOGENIC "IMMUNE" RNA. (E.) Deckers, P. J. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and Y. H. Filch. *Nature* 231(23):181-183, 1971.

Guinea pigs were given injections of cells from a benzopyrene-induced rat sarcoma containing tumor-specific transplantation antigens and after 9-11 days RNA was extracted from spleens and lymph nodes. This guinea pig RNA was used to immunize rats which were challenged with cells from a benzopyrene-induced sarcoma. RNA from immunized guinea pigs produced a resistance to challenge which exceeded the resistance manifested by unimmunized rats and by rats immunized with "nonspecific" RNA. By day 28 after challenge, only 5 of 20 rats given RNA from immunized guinea pigs had developed sarcomas, whereas 12 of 21 rats given "nonspecific" RNA and 17 of 21 unimmunized rats had developed sarcomas. In other experiments, RNA prepared from guinea pigs inoculated with benzopyrene-induced sarcomas containing tumor-specific transplantation antigen was used to immunize strain C₃H/HeN mice against sarcoma cell challenge. RNA from immunized guinea pigs protected mice against tumor development.

- 2429 ENHANCEMENT OF TUMOUR HOMOGRAFTS BY THE LOCAL GRAFT-VERSUS-HOST REACTION. (E.) Medzihradsky, J. (Cancer Res. Inst., Slovak Academy of Sciences, Bratislava, Czechoslovakia), M. Klobusicka, E. Konikova and L. Novotna. *Neoplasma* 18(2):133-140, 1971.

F₁ hybrid (Lw×BD) rats were challenged with MC-1 ascitic tumor cells and parental BD spleen cells by s.c. inoculation into the right flank; other F₁ hybrid (Lw×AVN) rats were given tritium-labeled spleen cell grafts by footpad injection. In animals challenged with both tumor and spleen cells, progressive tumor growth was observed in all animals compared to controls, which were given either mixtures of tumor with syngeneic spleen cells or tumor injections without spleen cells and in which regression occurred between 15-25

days following challenge. On the 6th day of the footpad-induced reaction (with parental spleen cells), ³H-thymidine injection resulted in the labeling of the small lymphocytes in the spleen; the label was steadily depleted until the 12th day when no label was found. Allogeneic spleen footpad injections showed 5% of small lymphocytes remaining labeled on day 12.

- 2430 INCREASED INCIDENCE OF SPONTANEOUS LUNG ADENOMAS IN MICE FOLLOWING NEONATAL THYMECTOMY. (E.) Trainin, N. (Dept. Exp. Biol., Weizmann Inst. Sci., Rehovot, Israel) and M. Linker-Israeli. *Israel J Med Sci* 7(1):36-41, 1971.

Inbred SWR/Jax mice were thymectomized at 3 days of age and the incidence of spontaneous lung adenomas arising in these animals was observed. Forty-percent of the thymectomized mice and 14% of the non-thymectomized mice developed tumors in 7 months. At the age of 13 months, tumor incidence in thymectomized and nonthymectomized animals was 44% and 14% resp. Thymectomized Swiss strain mice also developed lung tumors more frequently than nonthymectomized mice of the same strain. The number of peripheral blood lymphocytes was not significantly reduced after thymectomy in either SWR or Swiss mice; however, the immune response to sheep red blood cells was lower in thymectomized animals than in intact controls. In SWR mice, titers of hemolysins and hemagglutinins were decreased following thymectomy. Also impaired by thymectomy was the homograft response to tumor cell transplants; transplantation of a solid fibrosarcoma to intact and thymectomized mice resulted in 0% and 86% tumor takes, respectively.

- 2431 EFFECTS OF HETEROLOGOUS ANTILYMPHOCYTE ANTIBODY ON THE DEVELOPMENT OF SPONTANEOUS AND TRANSPLANTED LYMPHOMA IN AKR MICE. (E.) K. P. (Baylor Coll. Med., Houston, Tex.), K. S. and J. J. Trentin. *Cancer* 27(5):1161-1166, 1971.

Male pathogen-free AKR strain mice were given rabbit serum or rabbit anti-mouse thymocyte serum s.c. injections of 0.1 ml every third day and death the presence of absence of spontaneous lymphoma was noted. Untreated mice developed lymphoma at a rate of 52 wk of age; lymphoma incidence in mice given normal rabbit serum was similar to that in untreated mice. In mice given anti-lymphocyte serum (ALS), mortality from lymphoma was accelerated with 100% of mice dying with lymphoma by 48 wk of age. In a repeat experiment, accelerated spleen enlargement, probably leukemic, occurred; however, the time elapsed from commencement of treatment to death from leukemia did not differ appreciably between ALS-treated mice and in untreated controls. In a related experiment, ALS-treated mice were challenged with cells from a syngeneic thymoma. ALS treatment delayed death from thymoma in treated mice.

- 2432 RELEASE OF A NON-SPECIFIC CYTOTOXIC FACTOR BY SPLENIC CELLS IMMUNIZED AGAINST ALLOGENEIC TUMOUR CELLS. (E.) Hottier, D.

N.S.E.R.M., Vandoeuvre-les-Nancy, France), M. ner and C. Burg. *Rev Europ Etud Clin Biol* 3):240-243, 1971.

een cells from unimmunized Swiss B strain mice, from mice immunized against allogeneic tumor ls, were placed in one compartment of a 2-part mber. Tumor target cells prepared from a enzopyrene-induced rhabdomyosarcoma in Swiss B e were placed in the other compartment. unized mice received injections of a methylcho-threne-induced rhabdomyosarcoma of strain C₃H e. Both compartments were inserted beneath the n of a Swiss B strain mouse and allowed to remain place for 5-8 days; on removal from the mouse, or target cells in their compartment were counted. n tumor target cells were implanted in mice mpanied by spleen cells from an unimmunized se without added tumor cells or by spleen cells m an unimmunized mouse with allogeneic tumor cells, number of target cells recovered from their com- tment ranged from 1.39×10^6 cells/ml to $4.45 \times$ cells/ml. However, when tumor target cells e implanted in mice together with spleen cells m mice immunized against allogeneic tumor cells ytotoxic effect was seen to be operating on the or cells. Cell counts recovered from the tumor l compartment ranged from 0.23×10^6 cells/ml to 6×10^6 cells/ml.

3 RESISTANCE AND SUSCEPTIBILITY TO TUMOURS: V. ON THE PERMEATION OF THE ³H-THYMIDINE ELLED CELLS FROM LYMPHATIC ORGANS INTO THE SITE PROLIFERATING TUMOUR. (E.) Dvorak, R. (Dept. h., U. Hamburg, Germany) and J. Lindner. *plasma* 18(1):41-62, 1971.

e of strains BALB/c and CBA/j and Wistar strain s were given implantations of either Ehrlich ites carcinoma cells or Bo4 carcinoma cells intra- ally, or i.p.; tumor-bearing animals were given . injections of ³H-labeled lymphoid cells from een, lymph nodes, or thymus of syngeneic animals ch had been given repeated administrations of tri- ted thymidine. Labeled lymphoid cells were found monly in the lymph nodes and spleen, and more ely in the thymus, lung and liver, of tumor- ring animals. While no labeled lymphoid cells e found in the vicinity of the proliferating or transplants in rats, some labeled cells pene- ted to the upper lip of mice (the site of the nsplanted Bo4 carcinoma). In some cases, the ors of lymphoid cells had been immunized with ing tumor cells. In tumor-bearing rats given phoid cells from immunized donors the labeled phoid cells disintegrated more rapidly than el cells from unimmunized donors. In mice en lymphoid cells from immunized donors, there a slight increase in the number of labeled phoid cells in the region of the transplanted or. Some labeled fibroblasts were found in the nity of the Bo4 carcinoma; these fibroblasts e apparently transformed mononuclear lymphoid ls from the ³H-labeled inocula.

2434 INFLUENCE OF HOST FACTORS ON LEUKEMOGENESIS BY THE RADIATION LEUKEMIA VIRUS. (E.)

Haran-Ghera, N. (Dept. Exp. Biol., Weizmann Inst. Sci., Rehovot, Israel). *Israel J Med Sci* 7(1):17-25, 1971.

The leukemogenic activity of a cell-free centrifugate (CFC), prepared from a radiation leukemia virus-induced lymphoma was assayed by administration of the virus preparation into male C57BL/6 mice of varying immunological competence; virus was injected 1) i.p. into mice aged 24 hr or less, 2) into an 8-day-old isogenic thymus grafted under the kidney of thymec- tomized young adult hosts, a group of which were exposed to 400 R whole-body irradiation 3 days later or 3) into one lobe of the intact thymus of young adult animals, a group of which was exposed to 400 R whole-body irradiation 3 days later. The leukemo- genic agent induced 55% lymphoid tumors at an average latent period of 175 days in newborn mice, compared to 90% or 97% incidence and a latency of 84-95 days in irradiated mice which had received vi- rus injection into a thymus graft or into intact thy- mus; the incidence of lymphoid leukemia among mice in thymus inoculated groups that were not irradiated was 15-25%. Whole-body irradiation with buffer injection resulted in an 8% lymphoid leukemia inci- dence with an average latent period of 200 days. Virus-inoculated mice were also subjected to thymic irradiation, antithymocyte serum (ATS), normal rabbit serum (NRS) or urethan treatment. Local irradiation of thymus did not enhance tumor development, but ATS and urethan treatment increased leukemia induction 50% and 53%, resp., compared to virus inoculation alone; NRS had a slight co-leukemogenic effect. Delaying host treatment after inoculation of the leukemogenic virus into the thymus reduced the leu- kemia incidence in the different groups, although no decrease in virus viability in the thymus was found over a period of several wk; this decrease in leukemia development was attributed to an immuniza- tion phenomenon.

2435 PHYTOHEMAGGLUTININ UNRESPONSIVENESS IN MOUSE SPLEEN CELLS INDUCED BY METHYL- CHOLANTHRENE SARCOMAS. (E.) Adler, W. H. (Dept. Path., U. Florida Coll. Med., Gainesville) T.

Takiguchi and R. T. Smith. *Cancer Res* 31(6): 864-867, 1971.

The cellular composition of spleen cells from methylcholanthrene-induced tumor-bearing and tumor- free A/J and CBA mice was investigated using dis- continuous albumin density gradients. Normal spleen cells were predominantly dense, small lymph- ocytes while spleen cells from sarcoma-bearing mice were predominantly larger and less dense. The response to phytohemagglutinin (PHA) of spleen cells from tumor-bearing and tumor-free mice was observed; ³H-thymidine incorporation by cells from tumor-bear- ing animals was less responsive to PHA than were cells from tumor-free animals. Cells from tumor- bearing mice stimulated with PHA incorporated 41,326-63,951 cpm ³H-thymidine/culture while normals

incorporated 151,023 cpm/culture; spleen cells from tumor-bearing mice from which the tumors had been excised incorporated 143,846 cpm/culture. In another experiment, mice were immunized with sheep red blood cells (SRBC) and the response of their spleen cells to PHA was compared to that of unimmunized mice. Normal CBA mouse spleen cells stimulated with PHA incorporated 180,013 cpm ^3H -thymidine/culture, while spleen cells of mice immunized with 1 or 3 injections of SRBC incorporated 113,889 or 71,274 cpm/culture, resp. A shift in spleen cell cultures of immunized mice toward less dense cell types was also seen.

2436 RESISTANCE TO ROUS SARCOMA ELICITED BY IMMUNIZATION WITH LIVE VIRUS. (E.)

Sigel, M. M. (Dept. Microbiol., U. Miami Sch. Med., Fla.), P. Meyers and H. T. Holden. *Proc Soc Exp Biol Med* 137(1):142-146, 1971.

Chickens were immunized with subtumorigenic doses of Rous sarcoma virus (Rous-associated virus) once every 2 wk for 6 wk using a 10^{-8} dilution of virus; 3 wk after the last immunizing injection, birds were challenged with 100 tumorigenic doses of the Rous-associated sarcoma virus. While 100% of unimmunized chickens developed sarcoma, only 6% of immunized birds developed sarcoma. When immunization of chicks was effected with a 10^{-9} dilution of virus only 4% of birds developed tumors as a result of the immunizing virus injections compared to 25% of birds immunized with a 10^{-8} virus dilution. However, the 10^{-9} immunizing virus dose afforded only slight protection from tumor development to chickens challenged with virus following immunization. When chicks were immunized with a Rous-associated leukosis virus and challenged with Rous-associated sarcoma virus, 27% of birds immunized with 2 injections of Rous-associated leukosis virus and 9% of birds given 3 immunizing injections of virus developed sarcomas compared to 100% of unimmunized chickens. Neutralization tests on sera of immunized and unimmunized birds showed that 68 and 100%, resp., of sera from birds given 2 and 3 injections contained antiviral antibody; none of the sera from unimmunized birds contained antiviral antibody.

2437 EVIDENCE FOR COMMON ANTIGENIC SITES BETWEEN THE SURFACE OF SHEEP ERYTHROCYTES AND THAT OF CERTAIN VIRUS-TRANSFORMED HAMSTER CELLS. (Fr.)

Meyer, G. (Res. Dept. C.R.A.C.M., Marseille, France), C. de V. Saint Cyr and M.-A. Nosny. *C R Acad Sci* 272(14):1928-1931, 1971.

The membrane antigens of SV-40- or polyoma virus-transformed BHK cells appeared to be common to the surface antigens carried by sheep or guinea pig erythrocytes. Absorption methods revealed the antigens elicited by SV-40 transformation to have a constitution similar to that of the Forssman antigen, while the glycoproteins of the polyoma virus-transformed cells and the sheep erythrocyte appeared to differ from the Forssman antigen. Immunofluorescence showed the surface antigens of

hamster tumor cells (CT 54 strain) and the surface antigens of BHK 21/13 polyoma virus-infected cells to be specific to the viral infection and transformation. No such antigens were found on normal BHK 21/13 cells. The virus specific sites on the surface of the transformed cells were associated with an unmasking of a number of glycoprotein groups of which N-acetylgalactosamine and N-acetylglucosamine were the most frequent haptens. These molecules occurred on the surface of fresh or boiled sheep erythrocytes and on the surface of guinea pig erythrocytes and were common constituents of the Forssman type antigen. These data confirmed those found by O'Neil and Black.

2438 EVIDENCE FOR TUMOR-SPECIFIC IMMUNITY IN HUMAN MALIGNANT MELANOMA. (E.) Nag

G. A. (Dept. Internal Med., Bürgerspital, Switzerland), W. F. Piessens, M. M. Stilmant and F. Lejeune. *Europ J Cancer* 7(1):41-47, 1971.

Tumor cells and lymphocytes were collected from a 68-yr-old male patient with cutaneous malignant melanoma metastasizing to the regional lymph nodes. Lymphocytes taken from the patient on the day of resection of the tumor and at various times thereafter were reacted with tumor cells. Blastoid transformation of lymphocytes did not occur with lymphocytes taken on the day of the operation or reacted with tumor cells. However, lymphocytes taken on day 41 postoperation were stimulated by tumor cells; the stimulation was suppressed by autologous serum taken and stored on the day of operation. It was thought that lymphocyte transformation was an indicator of cell bound tumor specific immunity, and that immunity became manifest only after the removal of the primary tumor. Immunosuppressive serum taken on the day of operation was thought to have contained antibodies which blocked the lymphocyte stimulation.

2439 SERUM ALLOTYPE LOSS DUE TO A LYMPHOID TUMOR IN CHICKENS. (E.) David, C.

(Dept. Human Genetics, U. Michigan, Ann Arbor), O. J. Fletcher. *J Immunol* 106(6):1673-1676, 1971.

Loss of certain serum antigens upon tumor development was investigated in White Leghorn chickens. Thirty 6- to 10-wk-old chickens were inoculated with 0.5 ml of minced transplantable lymphoid material (TLT) in the pectoral muscle. Tumors developed within 4-5 days following inoculation. Three controls were used: 1) birds injected with normal lymphoid tissue; 2) birds injected with transplantable lymphoid tumor inactivated by freezing and thawing; and 3) birds without any treatment. Blood samples were taken by cardiac puncture and 7-13 days after tumor inoculation. The pre- and post-inoculation sera were tested for the typical antigens at the 3 genetic loci *a*, *b* and *c*. In 12 cases in which the pre-TLT serum was positive, the post-TLT serum failed to form a precipitin line. The 6 controls and 18 test birds gave clear precipitin lines for the 2 serum series.

allotype loss occurred most frequently with antigens C2 and C3. The *b* locus antigen disappeared only 3 cases; in the other cases either the *a* or *c* locus antigen disappeared. In 2 cases a positive reaction appeared in the post-TLT sera when it was negative in the pre-TLT sera. Except for the C2 and C3 antigens only one antigen at each locus disappeared. To check this observation, chickens were mated so as to obtain birds heterozygous at the 3 loci and injected similarly to TLT injection. The controls showed identical patterns for the pre- and post-TLT sera. In most cases only one of the antigens appeared to be inactivated. Allotype *a*1 was inactivated more often (5/9) in this experiment than in the first. The tumor mince came from a different group of birds for the second experiment. IgG was slightly depleted in the post-TLT sera when tested against rabbit antichickens whole serum. A band found close to the antigen well in the pre-TLT sera and suspected of being IgA was absent in the post-TLT sera. The allotype loss seemed to be due to a specific interaction with the growing tumor either by binding to neoplastic cells, thereby enhancing tumor growth, or by virus infiltration of specific stem cells, preventing further differentiation.

TUMOR IMMUNITY: TUMOR SUPPRESSION IN VIVO INITIATED BY SOLUBLE PRODUCTS OF SPECIFICALLY STIMULATED LYMPHOCYTES. (E.) Bernstein, D. (Div. Biol. Stand., Natl. Inst. Hlth., Bethesda, Md.), D. E. Thor, B. Zbar and H. J. Rapp. *Science* (1984):729-731, 1971.

Matched, adult, Sewall-Wright NIH inbred strain-2 guinea pigs were injected intradermally with 0.1 ml of ascites cells of transplanted diethylnitrosamine-induced hepatomas following immunization with migration inhibiting factor. On day 14, the intradermal tumor nodule measured 15 mm² and 9.3 mm² in control animals compared to lack of growth in immunized animals. At a site adjacent to the migration inhibiting factor-mediated rejection of tumor cells, the size of tumor papules on day 14 was 16.2-19.9 mm² in both immunized and control animals, indicating that a systemic adjuvant effect was not involved. Inhibition of growth of tumor cells implanted at sites of skin incisions 24 hr following immunization indicated that tumor rejection was due to the immune response of lymphocytes rather than to a direct effect by migration inhibiting factor.

TUMOR-ASSOCIATED IMMUNOGLOBULINS. (E.) Witz, I. P. (Dept. Microbiol., Tel Aviv Univ., Israel.). *Israel J Med Sci* 7(1):230-238, 1971.

Moloney lymphoma ascites cells removed from strain 2 mice 9-11 days after implantation were added to a mixture containing ¹³¹I-labeled globulin from rabbit anti-mouse globulin antiserum and ¹²⁵I-labeled normal rabbit globulin and incubated for 60 min at 37°C. Increasing numbers of Moloney lymphoma cells absorb increasing proportions of anti-immunoglobulin antibodies; label uptake was inhibited by the addition of excess unlabeled globulin isolated from the

same rabbit anti-mouse globulin antiserum. Tissue of primary benzo(a)pyrene-induced sarcomas contained at least 10 times more immunoglobulin (IgG) than normal tissue. A higher immunoglobulin IgG₂ fraction was eluted from fast growing tumors and from primary, rather than secondary, tumors. Tumor-associated immunoglobulins IgG₂ may represent specific antibodies directed against determinants of tumor cells.

2442 ANTILYMPHOCYTE SERUM AND ENHANCEMENT. (E.) Takasugi, M. (Dept. Med. Microbiol., U. California, Los Angeles) and W. H. Hildemann. *Israel J Med Sci* 7(1):221-229, 1971.

Antiserum produced in rabbits against Sarcoma I, an A strain tumor (Sa I), or anti-A/Sn spleen cell antiserum was injected into groups of A.BY mice previously inoculated with Sa I tumor cells. Three of 5 mice given anti-Sa I antiserum and 5 mice given anti-A/Sn spleen cell antiserum showed prolonged tumor survival time. Lymphocytosis accompanied the rejection of the tumor in untreated control mice, whereas treated mice challenged with Sa I showed a slight decrease in lymphocyte count on the day following treatment with recovery by day 4. Mice treated with antiserum and without tumor challenge exhibited a marked lymphopenia of several days. The present results confirmed that cytotoxic action against lymphocytes is a major cause of the decline in peripheral lymphocyte levels after anti-lymphocyte serum treatment.

2443 CARBOXY-TERMINAL STRUCTURE OF THE α CHAIN OF HUMAN IgA MYELOMA PROTEINS. (E.) Prahl, J. W. (California Inst. Tech., Pasadena), C. A. Abel and H. M. Grey. *Biochemistry* 10(10):1808-1812, 1971.

The α chains of several human IgA myeloma proteins were subjected to cyanogen bromide cleavage and the carboxy-terminal octapeptides of the proteins were isolated. The Edman degradation and sequence of the carboxy-terminal peptide was: (Met)-Ala-Glu-Val-Asp-Gly-Thr-Cys-Tyr. Proteins of the IgA₁ and IgA₂ protein subclasses showed the same sequence. The ultimate tyrosine residue was present in less than stoichiometric amounts, perhaps as a result of carboxypeptidic activity *in vivo*. It was found in the cleavage experiments using cyanogen bromide that the penultimate half-cystine must be present as an asymmetric inter-heavy-chain bond in order for it to be involved in disulfide bonding of polymeric forms.

2444 HAPTEN BINDING STUDIES ON MOUSE IgA MYELOMA PROTEINS WITH ANTIBODY ACTIVITY. (E.) Sher, A. (Salk Inst. Biol. Studies, San Diego, Calif.) and H. Tarikas. *J Immunol* 106(5):1227-1233, 1971.

The mouse IgA myeloma proteins S23, S63, S107, S129 and J539, having antibody specificities for either phosphorylcholine, ϵ -DNP-caproic acid or galactoside derivatives, were characterized in terms of affinity

for their respective haptens. The immunoglobulins were found to be homogeneous in their affinity for hapten and they showed association constants between 2×10^3 and 1.1×10^6 l/mole on equilibrium dialysis measurements. Binding activity was associated with the Fab fraction of each of the proteins. Unfractionated S107 protein in serum and the reduced and alkylated monomer purified by immunoadsorption had 2 sites/156,000 U molecular weight. Trypsin digestion of the S107 protein showed a Fab fraction in 64% yield with 1 site/53,000 molecular weight. Fractional numbers of binding sites were obtained using chromatography, gel filtration and repeated dialysis to purify the protein.

2445 HYPOLIPIDEMIA DURING MYELOMA. (Fr.)

Fiessinger, J.-N. (Lab. Clin. Chem., Paris, France), M.-P. Ollier, S. Filitti-Wurmser and L. Hartmann. *Ann Biol Clin* 29(1):25-37, 1971.

The serum lipid alterations occurring in 17 patients with IgA and 40 patients with IgG myeloma were reflected in lower levels of total lipids (decreased from 7 g/l in normal subjects to 4.8 g/l in IgA and to 6.3 g/l in IgG myeloma patients), of phospholipids (from 2.4 to 1.5 and 1.9 g/l, resp.), and of total cholesterol levels (from 2.2 to 1.3 and 1.8 g/l, resp.); no variations in the triglyceride levels were observed. α -Lipoprotein levels were decreased in 15 of 15 cases and the β -lipoproteins decreased in 9 of 15 IgA myeloma patients. Serum levels of α -lipoproteins were decreased in 25 of 36 patients with IgG myeloma, and β -lipoproteins were normal in 26 of 36 of these patients. Hypolipidemia was related to hypolipoproteinemia and appeared to be severe in IgA and minor in IgG myeloma patients. The average pathological globulin level was 38.4 g/l (ranging from 8-75 g/l) in sera from IgA myeloma patients and were associated with a decrease in albumin levels (from 43 to 34 g/l). The average pathological globulin level was 43.6 g/l (reaching 100 g/l in one case) in the IgG myeloma patients and seemed to vary according to its sudanophilic or non-sudanophilic properties. IgG elicited no sudanophilic properties; the sudanophilic properties were possibly due to variations in the γ_1 , γ_2 , γ_3 or γ_4 subgroup of the heavy chain constituents of the myeloma IgG. Analytical ultracentrifugation revealed at least 1 additional peak in 11 of 13 IgA myeloma sera and 6 sedimentation peaks in 5 of these sera as compared to the 3 S_1 , S_2 and S_3 sedimentation peaks occurring in normal sera; no supplementary sedimentation peaks were observed in the sera of 13 IgG myeloma patients. Correlation studies showed that hypolipoproteinemia involved mainly the α -lipoproteins. The protein alterations were not related to the type of the pathological immunoglobulin, and the decrease in lipids was more manifest with the increase in myeloma globulin, particularly in case of IgA myeloma.

2446 CELLULAR IMMUNITY INDUCED BY ROUS SARCOMA VIRUS IN JAPANESE QUAIL: I. EFFECT OF ANTILYMPHOCYTE SERUM ON ONCOGENESIS OF ROUS SARCOMA

VIRUS. (E.) Yamanouchi, K. (Dept. Measles Virus Natl. Inst. Hlth., Musashi-Murayama, Tokyo, Japan) and M. Hayami. *Jap J Med Sci Biol* 23(6):395-402, 1970.

Japanese quail spleen cells were inoculated into rabbits 3-4 times weekly; rabbits were bled at the end of the course of inoculations and the antilymphocyte serum (ALS) thus obtained was injected in amounts of 0.2 ml daily for 4 wk into Japanese quails. ALS-treated quails were subsequently infected in the wingweb with Schmidt-Ruppin strain sarcoma virus (100 ID₅₀). Tumors developing in quails not treated with ALS regressed in all cases, whereas only 2 of 9 tumors developing in quails treated with ALS regressed. All of 5 quails treated with normal rabbit serum instead of ALS and 6 of 6 untreated quails were resistant to a tumor-inducing dose of virus, while only 1 of 7 ALS-treated birds was resistant. Tumor metastases were found in liver, spleen and proventriculus of 3 of 7 ALS-treated birds, and in none of the control birds. 8 wk after virus challenge, 70% of quails in all experimental groups had developed virus-neutralizing antibodies.

2447 ANTIGENIC RELATIONSHIPS BETWEEN CELL MEMBRANES OF NORMAL AND SV40 TRANSFORMED RENAL KIDNEY CELLS. (E.) Kedar, E. (Dept. Immunology, Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel), M. Wiener, N. Goldblum and S. Sulitzeanu. *Israel J Med Sci* 7(1):132-142, 1971.

The antigenic relationships of cell lines derived from baby hamster kidney, hamster kidney cells transformed *in vitro* by SV40 and SV40-induced tumors were studied by means of rabbit antiserum against these tissue and sheep RBC. The antisera to the normal kidney cell membranes showed fluorescent antibody staining reactions of only 5-10% at all concentrations tested and the staining of tubular membranes were most pronounced; antisera to the tumor cell membranes stained the kidney glomeruli, the solid tumor cells and both cell lines intensely. Three antigens were distinguished: F antigen was present in all cell types, antigen in the glomeruli, and KT antigen was found mainly in the normal kidney tubules. Solid tumor cells bore less radioactivity than hamster kidney cells; specificity for binding was shown by the high degree of radioactivity bound to hamster kidney cells and leukemic cells in response to labeled antibodies specific to these cells.

2448 IMMUNOLOGIC RESPONSE OF MICE BEARING LEUKEMIA L1210. (E.) Bonmassar, E. (Microbiol. Assoc., Inc., Bethesda, Md.), A. Bonmassar, S. Vadlamudi and A. Goldin. *Cancer Res* 27(6):1356-1362, 1971.

The number of direct plaque-forming cells (PFC) in spleen was determined in normal and in leukemic mice at several stages of leukemic growth with or without therapy or following chemotherapy with an alkylating agent.

gent 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU). Mouse strains used included the oncogenic-resistant 7BL/10ScSn and the hybrid CDF₁ (DBA/c DBA/2 Cr male x BALB/c female). Mice were given injections of leukemic cells followed after 2, 3, 4 or 5 days of injections of antigenic sheep red blood cells (SRBC). When SRBC were injected 2 or 3 days after leukemic transplantation, PFC/spleen counts were normal or somewhat elevated ($10^{5.5}$ PFC/spleen). When SRBC were administered 4 or 5 days after the transplantation of leukemic cells, PFC/spleen counts were depressed (10^5 PFC/spleen). The antibody response seemed to be reduced only in mice subjected to antigenic stimulation after a certain stage of leukemic growth. In a related experiment, mice were immunized with SRBC following transplantation of fast- and slow-growing leukemic cells. Immunosuppression was seen only in mice given fast-growing leukemic cells in which SRBC was injected 5 days before the median day of death for mice; in contrast, immunosuppression was not seen in mice with slow-growing leukemia given SRBC 7 days before the median death day. Leukemia remission induced by BCNU did not prevent the immunosuppression of leukemic mice, although the same treatment schedule did not interfere with antibody production in non-leukemic animals.

49 VARIATION IN IMMUNOSENSITIVITY OF SV40-TRANSFORMED HAMSTER CELLS. (E.)

Veithia, S. S. (Baylor Coll. Med., Houston, Tex.), L. McMillan, P. M. Kaplan and S. C. Bushong. *Immun* 106(5):1295-1300, 1971.

Four-week-old hamsters were immunized by s.c. injections of 10^6 PFU of SV40 given once a wk for 3 wk and then challenged with cells from one of 2 cell lines derived from a hamster tumor originally infected by SV40; both these cell lines contained SV40 and T antigens. Of the 2 cell lines used to challenge the hamsters, one was immunosensitive (H-50 IS) and one was immunoresistant (H-50 IR). SV40-immunized hamsters rejected the challenge with H-50 IS cells; however, H-50 IR cells produced tumors in challenged hamsters. H-50 IR cells contained SV40-specific transplantation antigens; they rendered hamsters immune to challenge with H-50 IS cells. Both sensitive and resistant hamster tumor cells grew at the same rate *in vitro*, and both were inhibited to an equal degree by SV40 immune serum.

50 IMMUNOGLOBULIN, PROTEIN AND NUCLEIC ACID SYNTHESIS IN CULTURED MYELOMA CELLS. (E.)

Emmel, Ch. B. (Dept. Biol., U. Oregon, Eugene). *Cell Res* 65(1):202-208, 1971.

Cultured mouse myeloma cells were studied to determine the point at which the synthesis of immunoglobulin-coding messenger RNA molecules was most sensitive. Cultures in which overall cell growth had stopped showed the highest level of immunoglobulin synthesis relative to total protein synthesis; in these cultures, immunoglobulin synthesis amounted

to 30% of total protein synthesis. In cells where growth had ceased, however, total protein synthesis was low and since the production, content, and transport of RNA was constant at all times, it was concluded that the turnover of RNA in the nongrowing cells was high. Addition of fresh medium to the culture markedly increased cell turnover. While total protein synthesis in the late exponential stage of cell growth was similar to the exponential stage, the rate of immunoglobulin synthesis amounted to 10-20% and was on the increase. It was thought that the synthesis of immunoglobulin coding mRNA molecules was maximal at the late exponential phase of cell growth.

2451 POLYCLONAL IMMUNOGLOBULIN DEFICIENCY IN MYELOMATOSIS AND MACROGLOBULINAEMIA. (E.)

Cwynarski, M. T. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.) and S. Cohen. *Clin Exp Immun* 8(2):237-248, 1971.

Immunoglobulin (Ig) levels were compared in 118 patients with monoclonal protein disease (MPD) and it was found that polyclonal Ig was significantly reduced in 82% of the patients. Ig deficiency was equally frequent with all classes of monoclonal Ig, but was considerably more common in patients with myelomatosis than in patients with benign MPD. Normal values for electrophoretic heterogeneity and for proportions of κ - and λ -chains were found in polyclonal IgG taken from sera containing monoclonal IgG, IgA or IgM. In lymph nodes of patients with macroglobulinemia, monoclonal protein was synthesized; but monoclonal proteins were not synthesized by nodes from myelomatosis patients. Apparently spread of cancerous cells accounts for polyclonal Ig deficiency in macroglobulinemia but not in myelomatosis.

2452 INHIBITION OF MIGRATION OF HUMAN AUTOGENOUS AND ALLOGENEIC LEUKOCYTES BY EXTRACTS OF PATIENTS' CANCERS. (E.)

Wolberg, W. H. (Div. Clin. Oncol., U. Wisconsin Med. Ctr., Madison). *Cancer Res* 31(6):798-802, 1971.

Leukocytes and lymphocytes from peripheral blood were incorporated into Pasteur pipets with solution derived from normal or carcinomatous human tissue and studied for migration. Inhibition of leukocyte migration was found in 15 of 21 tumors tested and exceeded the migration seen with normal preparations in only 3 instances. Tissue preparations from a foreign body granuloma caused a 30% inhibition, whereas migration was unaffected by benign adenomatous polyps. Ultrasonic disruption of tumors produced preparations that effectively inhibited migration, and phytohemagglutinin produced inhibition of both leukocyte and lymphocyte migration dependent upon the concentration present in the migrating medium. 6-Mercaptopurine was effective in reversing the effect of phytohemagglutinin but not that of tumor preparations.

- 2453 THE INDUCTION OF PRECIPITATING ANTIBODIES TO THE MAMMARY TUMOR VIRUS IN SEVERAL INBRED MOUSE STRAINS. (E.) Hilgers, J. (Netherlands Cancer Inst., Amsterdam), J. H. Daams and P. Bentvelzen. *Israel J Med Sci* 7(1):154-160, 1971.

Mice of strains C57BL, 020, BALB/c, GR, C3Hf, Ceh, RIIIf, and RIII were injected i.p. with approximately 5 µg purified Bittner mammary tumor virus (MTV-S) preparation in Freund's adjuvant or with purified virus disrupted with ether; blood samples were taken 1-3 weeks after booster treatment of 20 µg of virus every 2-3 months. Antibodies to complete mammary tumor virus particles were detected in sera from immunized mice of every strain studied. Sera taken 21 days after the first booster with complete particles revealed that C3H and BALB/c gave no reaction at all. Most of the other sera reacted only with the P antigen (the virion and the assumed intact nucleoid). The RIII sera gave the strongest reactions with the P antigen, and, except for one 020 serum, they were the only sera which reacted with the membrane-soluble antigen of the disrupted virus. Sera taken after the 2nd booster showed strongest reactions when obtained at 14 days; a positive reaction was observed in each mouse strain to the complete virions at this time. After the 3rd and 4th booster, each mouse strain gave many positive reactions; C3H and BALB/c mice showed positive reactions with complete virions also. In female mice immunized with ether-treated virus and not given boosters, most sera reacted with nucleoid soluble antigen; GR and C57Bl strains failed to react with membrane soluble antigen.

- 2454 STUDIES ON CELLULAR AND HUMORAL IMMUNITY TO TUMOR-SPECIFIC ANTIGENS IN POLYOMA VIRUS-INDUCED TUMORS OF RATS. (E.) Datta, S. K. (Rega Inst. Med. Res., U. Leuven, Belgium) and M. Vandeputte. *Cancer Res* 31(6):882-889, 1971.

Inhibition of colony formation in cultures of polyoma sarcoma cells was studied with lymph node and spleen cells from R and BN inbred rats with polyoma virus-induced sarcomas. Lymph node and spleen cells that were sensitized specifically against polyoma tumor antigen and from animals infected with polyoma virus strongly inhibited colony formation by polyoma kidney sarcoma cells when compared with controls. Cells from 7 of 8 animals with primary tumor significantly reduced the colony number, and cells from all of 4 rats inoculated with virus as newborns showed a significant reduction in colony number. All of the 5 sera tested from primary tumor-bearing rats could block most of the inhibitory effect of lymph node and spleen cells from immunized rats or from rats with or without primary tumors, whereas all of the 5 sera from rats with no primary tumor had little or no effect; the blocking effect was specific since it was removable by absorption with polyoma tumor but not with a 7,12-dimethylbenz(a)anthracene-induced tumor. Sera from animals inoculated with the virus as newborns contained cytotoxic antibodies which reduced colony numbers when compared with normal serum.

- 2455 TUMOR-SPECIFIC IMMUNITY IN THE COURSE OF PRIMARY POLYOMA AND ROUS TUMOR DEVELOPMENT IN INTACT AND IMMUNOSUPPRESSED RATS. (E.) Sjöberg, H. O. (Dept. Immun., Fred Hutchinson Cancer Ctr., Pacific Northwest Res. Found., Seattle, Wash.) and K. Borum. *Cancer Res* 31(6):890-900, 1971.

A polyoma tumor and Rous sarcoma resulting from infection of inbred W/Fu and BN rats that were either untreated, inoculated with antilymphocytic serum after infection, thymectomized or sham-operated were utilized for the study of colony inhibitory effects on tumor target cells of rats with or without primary tumors. Significantly higher frequencies of primary tumors were obtained in immunosuppressed animals; although the frequency of primary Rous sarcoma was 100% in both immunologically intact and immunosuppressed rats, a somewhat reduced latency period was seen in the latter. Cell-mediated immunity tests to the tumor-specific transplant antigens of polyoma and Rous sarcomas revealed that lymph node cells of the rat carrying a primary polyoma sarcoma did not inhibit the polyoma target tumor cells, but they significantly inhibited the Rous sarcoma target cells. Sera from 3 of 7 rats carrying primary polyoma tumors has a significant inhibitory effect on the polyoma target tumor cells but did not inhibit Rous sarcoma cells, showing the inhibitory effect is specific.

- 2456 COMPLEMENT FIXATION IN CONVENTIONAL AND REGRESSING VIRUS-INDUCED MURINE LEUKEMIA. (E.) Rich, M.A. (Albert Einstein Med. Ctr., Philadelphia, Pa.), S. Karl and R. Clymer. *J Immunol* 106(6):1488-1492, 1971.

The complement fixation (CF) antibody response of Swiss mice following infection with the regressor Friend virus (RFV) strain was compared to that elicited by conventional strains of murine leukemia virus. Random-bred ICR/Ha Swiss male mice, 4-5 weeks old, were inoculated i.p. with 0.5 ml containing 200 ED₅₀ doses of cell-free virus stocks prepared from 20% suspensions of spleens from leukemic mice previously inoculated with conventional or regressor FV. Sera were obtained 50 days later from mice leukemic by 18 days after inoculation. "regressed" sera were taken from mice leukemic by day 18 and non-leukemic by day 50. Immunization with a conventional strain of murine FV led to an appreciable humoral CF response. RFV-infection led to the appearance of CF antibody in mice in which leukemia had regressed and was absent in leukemic mice. This CF antibody cross-reacted with other strains of murine leukemia virus.

- 2457 THE GROUP-SPECIFIC ANTIGEN AND OTHER TUMORAL PROTEINS OF HAMSTER AND MOUSE CARCINOGENESIS ABSTRACTS 1971. (E.) Oroszlan, S. (Flow Lab. Inc., Rockville, Md.), C. Foreman, G. Kelloff and R. V. Gilden. *Virology* 43(3):665-674, 1971.

Monolayers of hamster embryo cells chronically infected with hamster specific helper virus and rat tumor

carrying the AKR leukemia virus were incubated in medium containing ^3H -uridine and ^3H -amino acids and studied for the presence of group-specific antigen and other structural proteins. Cultures were analyzed by sucrose gradient centrifugation, and clear visualization of ^3H -amino acid label was found at buoyant density of approximately 1.15 g/cm^3 . The protein content of pooled peak fractions totalled $10 \mu\text{g}$, based on absorbance values, with a specific activity of 1.3 complement fixation U/ μg protein of mouse antiserum. Animals immunized with 0.75 of the pH 6.9 fraction provided antisera which were specific for hamster C-type viruses in complement fixation and gel diffusion tests and which were non-reactive with uninfected hamster cells, ether-disrupted murine C-type viruses and its group specific antigen. Studies employing polyacrylamide gel electrophoresis of amino acid-labeled hamster and mouse C-type viruses disrupted by SDS, urea and mercaptoethanol revealed 3 major polypeptides for each virus; their molecular weights were 14,000, 17,500 and 30,000 for hamster virus and 14,000, 23,000 and 35,000 for the mouse virus.

8 RETENTION OF ANTIGEN SPECIFICITY OF MURINE SARCOMA VIRUSES GROWN IN HAMSTER CELLS *IN VITRO*. (E.) Kelloff, G. (Nat'l. Cancer Inst., Div. 1. Inst. Hlth., Bethesda, Md.), R. J. Huebner, H. Chang, S. Oroszlan and R. V. Gilden. *Nature* (5):155-157, 1971.

Neutralization tests were carried out by the focus reduction procedure using 3 sarcoma viruses (a hamster-specific sarcoma virus, M-MSV(HaLV)G; a Rauscher leukodermatoma virus, M-MSV(RLV)/HEF; and a Moloney sarcoma virus, M-MSV(RLV)G grown exclusively on mouse cells) and antisera (anti-M-MSV(HaLV)G from tumor-bearing hamsters and anti-RLV from hamsters immunized with Rauscher leukemia virus-hamster tumors). M-MSV(RLV), whether grown in hamster cell or not, was neutralized by anti-M-MSV(HaLV)G and was not neutralized by anti-M-MSV(RLV)G; M-MSV(HaLV)G was neutralized by its homologous antiserum but not by anti-RLV. Interference tests showed that the helper virus, HaLV, interfered with M-MSV(HaLV)G but not with M-MSV(RLV)/HEF, indicating that the latter does not share envelope antigens with the hamster-specific viruses. The interference mediated by HaLV seems to be specific for hamster viruses and a non-interferon mediated interference. Immunodiffusion and complement-fixation tests showed that M-MSV(RLV)/HEF maintained group-specific antigen after growth in hamster cells and showed no reactivity with antisera against the hamster group-specific antigen. *In vitro* passage of murine sarcoma virus in hamster cells does not seem to cause the complete hamster-specific host range and antigenic change seen after *in vivo* passage in the hamster.

9 THE ADOPTIVE TRANSFER OF CONCOMITANT IMMUNITY TO MURINE TUMOR ISOGRAFTS WITH TUMOR CELLS FROM TUMOR-BEARING ANIMALS. (E.) Kiers, P. J. (Surg. Brnch., Nat'l. Cancer Inst., Bethesda, Md.), B. W. Edgerton, B. S. Thomas and Y. H. Pilch. *Cancer Res* 31(6):734-742, 1971.

Mice of the C57Bl/6 strain were given immunizing or control treatments as follows: 1125 mice were given s.c. inoculations of 10^5 viable cells of a methylcholanthrene-induced sarcoma in the right hind leg; of the 1125 animals given tumor cells, groups of 25 were challenged with injections of 5×10^3 sarcoma cells in the left hind leg 1-28 days after the initial tumor inoculation; some tumor-bearing mice were killed and used as donors of spleen cells which were injected i.p. into previously untreated mice; mice given spleen cells were challenged with tumors 1-21 days after spleen cell inoculation. In mice given an immunizing inoculation of sarcoma cells the challenge inocula took in 0-8% of animals challenged on day 7-28 after tumor cell transfer. The tumor incidence in controls which received no immunizing tumor inoculation was 87-100%. Mice given spleen cells from tumor-bearing mice showed delay in tumor development and reduced tumor incidence compared to mice given spleen cells from tumor-free mice and compared to mice given tumor cell inoculations only.

2460 EFFECT OF SYNGENEIC AND ALLOGENEIC PLASMA ON LYMPHOCYTES FROM CANCER PATIENTS, PATIENTS WITH NON-NEOPLASTIC DISEASES, AND NORMAL SUBJECTS. (E.) Al-Sarraf, M. (Div. Oncol., Wayne State U., Detroit, Mich.), S. Sardesai and V. K. Vaitkevicius. *Cancer* 27(6):1426-1432, 1971.

Blood lymphocytes from cancer patients were cultured with syngeneic plasma or allogeneic plasma (from non-cancer patients or from healthy subjects); lymphocytes were stimulated with phytohemagglutinin, and the blast transformation and mitotic response of the cancer patients' lymphocytes were observed in culture with syngeneic and allogeneic plasma. Blast transformation and mitotic response of cancer patients' lymphocytes were inhibited by allogeneic plasma of either non-cancer patients or healthy subjects. Transformation of lymphocyte from non-cancer patients was also inhibited when plasma from cancer patients or from healthy subjects was added to them in culture. Plasma from cancer patients and from non-cancer patients also inhibited the transformation response of lymphocytes from healthy subjects.

2461 LEUKOCYTE CANDIDACIDAL ACTIVITY AND RESISTANCE TO SYSTEMIC CANDIDIASIS IN PATIENTS WITH CANCER. (E.) Lehrer, R. I. (Cancer Res. Inst., U. California Med. Sch. San Francisco) and M. J. Cline. *Cancer* 27(5):1211-1217, 1971.

Leukocytes collected from patients with metastatic solid tumors, lymphoma, Hodgkin's disease (stages I-IV) and multiple myeloma were incubated with the pathogen *Candida albicans*. The ability of the leukocytes to ingest and/or kill the pathogen was observed. While neutrophils from patients with neoplastic disease were able to ingest *Candida*, cells from patients with advanced Hodgkin's disease and with acute leukemia showed impaired ability to kill *Candida*. Patients with metastatic tumors on chemotherapeutic regimens also showed impaired candidacidal capacity. Some of the neutrophils which

showed diminished candidacidal activity also showed low levels of myeloperoxidase and lysozyme activity. Deficient candidacidal activity may place certain cancer patients at high risk of developing systemic candidiasis.

- 2462 STUDIES CONCERNING THE REGIONAL LYMPH NODE IN CANCER. (E.) Fisher, B. (U. Pittsburg Sch. Med., Pa.) and E. R. Fisher. *Cancer* 27(5):1001-1004, 1971.

The popliteal and lateral lymph nodes were removed from the left hind legs of female strain C3HeB/FeJ mice 7 days prior to implantation of an immunizing extract from a spontaneous C3H mammary carcinoma in the left hind leg. Seven days after tumor implantation, the treated legs were amputated and 3 wk after amputation mice were challenged with 10^4 viable tumor cells from the tumor used for immunization. Removal of lymph nodes prior to implantation of tumors resulted in a failure of animals to develop sinecomitant immunity; when lymph nodes remained intact, sinecomitant immunity was manifested. By wk 12 after tumor cell challenge, 53% of mice with lymph nodes removed and 32% of animals with lymph nodes intact had developed tumors. Animals with tumors growing for 28 days in the absence of regional lymph nodes failed to develop concomitant tumor immunity to the same degree as animals with tumors and intact regional nodes. In the former group, tumor incidence amounted to 64% and in the latter group, tumor incidence amounted to 30%.

- 2463 ANTIBODY TO EPSTEIN-BARR VIRUS IN AMERICAN PATIENTS WITH CARCINOMA OF THE NASOPHARYNX. (E.) Goldman, J. M. (Massachusetts General Hospital, Boston), M. L. Goodman and D. Miller. *Jama* 216(13):1618-1622, 1971.

- 2464 TRANSFER OF TUMOR IMMUNITY WITH RNA. (E.) Pilch, Y. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), K. P. Ramming and F. Deckers. *Israel J Med Sci* 7(1):246-258, 1971.

- 2465 EVIDENCE OF THE PARTICIPATION OF DEOXYRIBONUCLEIC ACID IN LATE IN CANCER IMMUNITY. (E.) Vlcek, J. (Inst. Radiation Hygiene, Prague, Czechoslovakia), A. Reif and B. Seidlova. *Z Naturforsch* 26(5):414-424, 1971.

- 2466 IMMUNOSUPPRESSION: A PARANEOPlastic SYNDROME. (Ger.) Nagel, G. A. (Basel Univ. Clin., Switzerland). *Schweiz Med Wschr* 101(13):474, 1971.

PATHOGENESIS

67 CHROMOSOMES OF PRECANCEROUS LESIONS OF THE CERVIX UTERI: NEW DATA AND A REVIEW. (E.)
 Riggs, A. I. (Churchill Hosp., Oxford, England),
 E. Bowey and R. H. Cowdell. *Cancer* 27(5):1239-1254,
 1971.

ne biopsies were made on the anterior and posterior
 ects of the cervix uteri of 28 patients with
 eplasia, carcinoma *in situ* and microcarcinoma of
 e cervix; cytogenetic examinations were performed
 the biopsy material. In some cases it appeared
 at the same cell clone was present on both aspects
 the cervix; in these cases an abnormal chromosome
 mber or a distinctive marker chromosome was seen
 both samples of biopsy material. In 2 cases the
 esence of marker chromosomes on opposite sides of
 e os made the relatedness of the 2 cell clones
 equivocal. One of these cases involved severe
 cervical dysplasia with no invasion and the other
 involved severe dysplasia and carcinoma *in situ*.
 e biopsy material showed wide variation in chromo-
 me counts, which grouped at or below 46, in the
 85 region or near 92. Populations with counts in
 e 75-89 region occurred only in cervixes affected
 th microcarcinoma or with *in situ* carcinoma. Nor-
 al diploid cells were rare and marker chromosomes
 re found in 7 of 9 cases of microcarcinoma and in
 of 18 cases of non-invasive carcinoma. No chromo-
 al disorder or marker chromosome was distinctive
 any of the clinical conditions observed.

8 MICROSPECTROPHOTOMETRIC DETERMINATIONS OF
 PROTEIN SULFHYDRYL GROUPS IN THE EPITHELIUM
 ENDOMETRIAL GLANDS IN HYPERPLASIA AND CANCER.
 s.) Kazantseva, I. A. (Inst. Human Morphol., Acad.
 . Sci., Moscow, U.S.S.R.) and N. P. Krut'kovskaya.
 11 *Eksp Biol Med* 71(3):79-81, 1971.

rospectrophotometry of material obtained from 20
 ometrial smears (of 5 healthy women, during the
 0th day of the menstrual cycle, 5 women with
 ndular cystic hyperplasia, 5 women with adenoma-
 s hyperplasia and 5 women with adenocarcinoma) was
 ormed to determine the variations in protein SH
 up levels. The concentration in SH groups
 ressed in relative optical density was 0.14-0.17
 the cytoplasm of normal or glandular hyperplastic
 ometrial epithelium and 0.21-0.28 in that of
 omatous hyperplasia or adenocarcinoma of the
 ometrium. The nucleoli and the nuclei had 0.33
 0.21 optical density concentrations of SH groups,
 ., in adenocarcinoma and 0.20 and 0.14, resp., in
 omatous hyperplasia and glandular cystic hyper-
 sia. The concentration of protein sulfhydryl
 ups was almost the same in the nucleus and cyto-
 sm and only slightly higher in the nucleolus of
 al endometrial epithelial cells. Decreases of
 nucleus/cytoplasmic ratio were also observed,
 , 0.88 in glandular cystic hyperplasia; 0.63 in
 omatous hyperplasia and 0.64 in adenocarcinoma
 pared to 0.98 in normal cells. The significant
 ges in the normal concentration of protein sulf-
 yl groups in the nucleus and cytoplasm of epithel-
 cells in precancerous hyperplasia and carcinoma
 the endometrium appear to be one of the reasons

for the increased number of metaphases and the marked
 increase in the number of pathological mitoses.

2469 THE GROWTH HORMONE IN PATIENTS WITH CANCER
 OF THE UTERUS AND OF THE MAMMARY GLAND:
 ITS RESISTENCE TO GLUCOSE SUPPRESSION. (Rus.)
 Bobrov, Yu. F. (N. N. Petrov Sci. Res. Inst. Oncol.
 Leningrad, U.S.S.R.), S. V. Patokin and V. M.
 Dil'man. *Vop Onkol* 17(3):40-44, 1971.

Growth hormone (GH) levels in blood samples decreased
 1 hr after 1.5 g/kg glucose intake by 37% in 13
 27-yr-old control subjects and by 43% in 13 40-yr-
 old subjects; serum GH and FFA increased by 50% in
 14 middle-aged (53-yr-old) subjects, by 43% in 9
 patients (47-yr-old) with mammary gland cancer and
 by 5-14% in 17 patients (50-58-yr-old) with uterine
 cancer. FFA levels decreased by 45% in the young
 control group, by 10% in the middle-aged group and
 by 16% in patients with uterine cancer. The alter-
 ations in GH suppression by glucose under the
 experimental conditions appeared to be more manifest
 in patients with mammary gland tumor than in those
 with uterine cancer, although alterations of carbo-
 hydrate metabolism occur more often in the latter.
 The loss of GH control appeared to be a result of
 an increase of the hypothalamic threshold for glu-
 cose regulation; such an increase may induce a set
 of metabolic alterations specific to ageing weight
 gain, prediabetes, hypercholesterolemia, athero-
 sclerosis and to conditions promoting neoplasia.

2470 ENZYME HISTOCHEMICAL OBSERVATIONS IN VARIOUS
 FUNCTIONAL PHASES AND IN PATHOLOGICAL
 CHANGES. (Ger.) Bässler, R. (Inst. Pathol., U.
 Mainz, Germany). *Acta Histochem Suppl.* No. 9:605-
 612, 1971.

Histochemical and electron microscopic studies show
 that the administration of estrogens, progesterone
 and prolactin to young female rats elicits
 increased enzyme activities in the mammary epithelial
 cells reaching maximal levels 5 days after treatment
 and plateauing at constant values thereafter. Estro-
 gen treatment produced the most pronounced effects.
 Marked changes were seen in the phosphatases, dehydro-
 genases, nonspecific esterases, ATPase, monoamineoxi-
 dase and 5'-nucleotidase. During lactation, exogenous
 hormones elicited markedly higher enzyme activities
 than those seen during pregnancy or the involutinal
 phase. Topochemically, the phosphatases were selec-
 tively localized in the cell membrane and in the basal
 folds of the glandular epithelium. The increased
 activities of alkaline phosphatase in human mammary
 gland and mammary gland carcinoma tissues (according
 to available data) were considered to be estrogen-
 induced.

2471 LIVER CANCER IN RATS WITH DIETARY CIRRHOSIS.
 (Rus.) Volgarev, M. N. (Natr. Inst. Acad.
 Med. Sci., U.S.S.R., Moscow). *Arkh Pat* 33(2):38-43,
 1971.

Of a total of 262 heterozygotic male rats divided into 4 experimental groups and feed 3 different types of cirrhosis-inducing diets deficient in proteins and the methionine and choline, 73 animals developed histopathologically confirmed hepatic cirrhosis at the end of eleven months. Thirty-four of these 73 cirrhotic rats were then transferred to a completely balanced nutritional diet for periods of 4-15½ months; hepatic cell carcinomas developed in 5 of the 34 rats; it is emphasized that only the cirrhotic rats transferred to a nutritional diet developed liver carcinomas and that none of the animals maintained on the cirrhosis-inducing diets developed neoplasms.

- 2472 THE RELATIONSHIP BETWEEN LUNG CANCER AND TUBERCULOSIS. (Rus.) Rabukhin, A. Ye. (Central Postgrad. Med. Inst., Moscow, U.S.S.R.) and M. Z. Upiter. *Vop Onkol* 17(3):24-32, 1971.

Epidemiological and pathogenic aspects of the relationship between tuberculosis and malignant neoplasia of the respiratory system are discussed. From data accumulated between 1967-1969 in several clinical units of Moscow, the incidence of malignant neoplasia appears to be 4-4.5-fold higher among male tuberculosis patients above 50-yr-old compared to the normal population. Of 161 patients with coexisting lung tuberculosis and cancer, 2/3 seem to have developed neoplasia from various preceding alterations of the pulmonary tissue such as calcification foci of meta-tuberculous scleroses. Of 370 patients with neoplasia, confirmed by fluorography, 112 (30%) exhibited various alterations of tuberculous nature: 1.8% had an active focal process; 18.4% had focal fibrotic or sclerotic alterations of the lung; 9.8% had calcifications within the lymphatic nodes of the chest. Among the patients with monolobular tuberculosis 61% developed homolobular neoplasia and 30% developed homosegmental neoplasia. The role of tuberculosis as a process causing chronic trauma and as a specific carcinogenic factor is reviewed.

- 2473 THE PATHOGENESIS OF PULMONARY CARCINOMATOUS LYMPHANGIOSIS. (Ger.) Schermuly, W. (Surg. Clin., Marburg Univ., Germany) and D. Schaefer. *Strahlentherapie* 141(5):508-517, 1971.

The development of metastases from pulmonary tumors, particularly in the case of lymphangiosis, was investigated and an attempt was made to reconstruct the metastasizing pathways by means of comparative pathological and X-ray findings. Such pathways were traced between 11 hilifugal and 12 hilipetal processes and the lymphangiosis. In one case the lymphangiosis was shown to originate from a single metastatic round focus and in 4 cases from a peripheral pulmonary tumor. A diffuse lymphangiosis possibly derived from a hematogenic carcinoma, developed metastases in all the pulmonary sections.

- 2474 INITIATION OF MALIGNANT TRANSFORMATION AND THE SIGNIFICANCE OF CHANGES IN TRANSFER RNA METHYLASE ENZYMES. (E.) Pillinger, D. J.

(Christie Hosp., Manchester, England) and R. Wilkinson. *Cancer Res* 31(5):630-632, 1971.

Syrian hamster kidney cell lines (normal, spontaneously transformed, and an established tumor line agar plating efficiencies of 2.3%, 15% and 38% resp.) were used to prepare a nonparticulate supernatant fraction for soluble cell component extraction to study the ability of this fraction to incorporate methyl groups from S-adenosyl-L-methionine-methyl-¹⁴C into methyl-deficient *Escherichia coli* tRNA. Spectrophotometric radioactivity assay revealed a 2-fold elevation of the enzymes extracted from the established tumor cell over the normal cells and a less marked elevation in the spontaneously transformed cell line. Morphologically normal cells injected into hamsters at the time of the assay subsequently produced malignant transplantable tumors, indicating a similarity in the methylase enzymes between morphologically normal but tumor-producing hamster kidney cells and the recognizable transformed cells.

- 2475 SERYL TRANSFER RNA CHANGES DURING ESTROGEN-INDUCED PHOSVITIN SYNTHESIS AND UNIQUE SERYL TRANSFER RNA MODIFICATION. (E.) Pick, M. R. (Stanford U. Sch. Med., Cal.) and Mäenpää. *Cancer Res* 31(5):684-687, 1971.

The serine acceptance of hepatic tRNA prepared from estrogen-treated roosters that synthesize phosphovitin (a yolk protein containing greater than 50% serine residues which are nearly all phosphorylated) at a rapid rate was more than 25% greater than that of hepatic tRNA from control roosters. Major differences were seen with seryl-tRNA when the labeled hepatic aminoacyl-tRNA's from control and estrogen-treated animals were compared. Seryl-tRNA from estrogen-treated animals was enriched in 1 major and in 1 minor peak, but no significant differences were observed with the other aminoacyl-tRNA's. The changes in seryl-tRNA correlated with changes in plasma phosphovitin. The seryl-tRNA peaks were characterized by examination of their amino acid composition and their codon response. Paper chromatography products of deacylation revealed that all products contained serine but that the product of peak 4 contained O-phosphoryl-L-serine. Peak 4 was found to contain a unique tRNA^{Ser} species for phosphoserine. Three of the 4 serine tRNA peaks responded to the known serine codons, but peak 4 did not respond and showed only slight binding to poly (U,C). This unusual aminoacyl tRNA may have a unique function in metazoan cellular regulation.

- 2476 PLASMINOGEN ACTIVATOR OF THE BLOOD VESSELS IN TUMOURS AND IN CARRAGEENAN-INDUCED GRANULOMAS. (E.) Pick, C. R. (Dept. Pathology, U. Cambridge, England) and D. B. Catcott. *Brit J Exp Path* 52(1):14-22, 1971.

Cryostat sections of tumor or granulomas from hamsters and mice were incubated on fibrin-covered slides containing plasminogen or no plasminogen from 1

more hr. Fibrinolysis was localized in human and at tissue around mature and small vessels in the stroma which reacted to the invading cancer cells. Fibrinolysis was seen in the plasminogen-free control slides. Systemic injection of inflammatory agents had no effect on fibrinolytic activity of the vessels.

2477 GLYCOLIPID SYNTHESIS IN NORMAL AND TRANSFORMED ANIMAL CELLS. (E.) Robbins, P. (Imperial Cancer Res. Fund, London, England) and J. A. Macpherson. *Proc Roy Soc Lond* 177(1046):49-58, 1971.

The incorporation of ^{14}C -labeled palmitate-1 into cellular lipids was measured in normal and transformed hamster cells *in vitro* to investigate the synthesis of glycolipids in these cell systems. Ceramide monohexoside, ceramide dihexoside and hemasphingoside were present in comparable amounts in normal and in transformed cells; however, 3 larger glycolipids, namely an unknown ceramide which generated

ceramide dihexoside on partial acid hydrolysis (CX), ceramide tetrahexoside (AGL) and ceramide trihexoside (CTH), were consistently absent from transformed cells. In actively growing untransformed hamster cells CX, AGL and CTH were present in smaller amounts than in contact-inhibited hamster cells. It was thought that the disruption of the normal mechanisms of contact inhibition by transformation may have resulted in a lower content of complex glycolipids.

2478 MICROGLANDULAR ENDOCERVICAL HYPERPLASIA ASSOCIATED WITH ORAL CONTRACEPTIVES. (Ser.) Damjanov, I. (Zagreb Med. Inst., Yugoslavia). *Liječnički Vjesnik* 92(9):1049-1054, 1970.

- 2479 THE RISING INCIDENCE OF CANCER OF THE PANCREAS--FURTHER EPIDEMIOLOGIC STUDIES. (E.) Krain, L. S. (Los Angeles, Calif.). *J Chronic Dis* 23(10-11):685-690, 1971.

The incidence and distribution of cancer of the pancreas was investigated in a survey of cases recorded in the California Tumor Registry. The number of observed cases of pancreatic cancer recorded from public county hospitals was 784 among males compared to an expected number of 666 cases; on the other hand, the numbers of observed and expected cases of pancreatic cancer among male patients in private hospitals were 849 and 967, resp. A high incidence of pancreatic cancer was found among Negroes; the incidence in the Negro population in the study was 13 cases/100,000 population for males, while incidences for white and Chinese males were 9.6 and 11.1 cases/100,000, resp. The high Negro incidence did not explain the rising annual incidence of pancreatic cancer mortality in the United States, which has amounted to 300% since 1920. Some etiological factors which may be associated with the increased mortality are smoking, alcoholism and occupational exposure to carcinogens.

- 2480 CARCINOMA OF THE ENDOMETRIUM: A STUDY OF CHANGING RATES OVER A 15-YEAR PERIOD. (E.) Christopherson, W. M. (U. Louisville School Med., Ky.), W. M. Mendez, J. E. Parker, F. E. Lundin and E. M. Ahuja. *Cancer* 27(5):1005-1008, 1971.

The incidence of endometrial carcinoma was investigated among the female population of the Louisville-Jefferson County area in Kentucky during the period 1953-1967; during the study period there were 707 histologically proven cases of adenocarcinoma of the endometrium, with an average incidence rate of 23.8 cases/100,000 population for women 20-yr-old and above. The rate of incidence for endometrial carcinoma among Caucasian women was 52% higher than the rate for Negro women for all women under 70-yr-old; among women 70-yr-old or over, the rate among Negroes was higher than the Caucasian rate. The risk of developing endometrial carcinoma was found to be 4 times higher for women 60-yr-old or more than for women 20-60-yr-old. The average age of endometrial carcinoma patients was 59.6-yr-old for Caucasian women and 64.4-yr-old for Negro women. When average yearly endometrial carcinoma rates from the period 1953-1955 were compared with the rates from the period 1965-1967, a 26.3% increase in incidence was found; however, the increase was not statistically significant when the incidence rates were corrected for aging of the population.

- 2481 EPIDEMIOLOGY OF MALIGNANT MESOTHELIOMA IN HAMBURG: A PRELIMINARY REPORT. (E.) Bohlig, H. (Munic. Hosp., Lubdenscheid, Germany), A. F. Dabbert, P. Dalquen, E. Hain and I. Hinz. *Environ Res* 3(5/6):365-372, 1970.

More than 250 cases of diffuse malignant mesothelioma involving the possibility of occupational, urban or

residential exposure to asbestos dust were found record in Hamburg (1,860,000 population) between 1958 and 1968. Of these 250, 119 case histories were provided with residence and occupational data; the other cases were lacking either occupational residential exposure information and 60 cases had no data on smoking habits. Of the 119 cases, 10 patients lived within the urban area, including mesotheliomas detected in the district of Berged surrounding an asbestos factory. Occupational exposure to asbestos could be ascertained in 54 of the 119 cases; 12 were specifically asbestos workers, 17 were shipbuilding workers. The latency period for the development of mesothelioma appeared to be 10 yr longer (40 yr) in shipyard workers than in workers involved in asbestos factories (30 yr). Urban exposure to asbestos was apparently associated with dust emission from asbestos processing industries which have been brought under control during the last 20 yr.

- 2482 LUNG CANCER IN THE URBAN ENVIRONMENT. (Rus.) Fershtudt, V. I. (Inst. Exper. Clin. Oncol. Acad. Med. Sci., U.S.S.R., Moscow). *Klin Med* 48(12):52-55, 1970.

A retrospective epidemiological study based on certificates and medical records, of lung cancer mortality in Moscow during the years 1958-1959, 1962 and 1964-1965 shows a significant and general continued increase in lung cancer deaths. In 1958 the number of lung cancer deaths in males was 7 compared to 25.3% in 1959; in females, the respective figures were 4.3% and 7.3%. In 1965, male lung cancer deaths were 28%, female rates 7.3%. Lung cancer mortality was increased at age 40 for males and at age 50 for females. Even though the mortality for both sexes in the 50-59 age group was somewhat higher in 1961-62 than in 1958-59, in 1964-65 there was a significant increase in the number of male deaths in all age groups as compared to the mortality in previous years (1958-59, 1961-62). The increase in lung cancer cannot be attributed to improved diagnostic techniques since a comparable increase has not been observed in females. Standardized mortality rates per 100,000 population in various districts of Moscow indicate a higher lung cancer death rate among males living in industrialized areas; in 10 of these districts the male mortality rate is 1.5 times higher than in females. A preliminary analysis of 4 districts shows that male lung cancer victims are significantly more exposed to the effects of industrial pollutants than are females.

- 2483 LYMPHOGRANULOMATOSIS IN CHILDREN OF THE BULGARIAN PEOPLE'S REPUBLIC (1960-1964). (Rus.) Doncheva-Strateva, N. (Postgrad. Med. Inst., Sofia, Bulgaria). *Vop Onkol* 17(3):33-35, 1971.

During the period 1960-1964, an average annual incidence of malignant neoplasia of 15.6/100,000 was reported in children in Bulgaria. Lymphogranulomatosis constituted 7.8% of these cases and appeared to have the lowest incidence among the various types of malignant neoplasms.

cies with an average of 1.2/100,000 (1.5 for boys and 0.9 for girls). The highest incidence of this disease occurred at the age of 10-14 yr (2.1/100,000 for boys and 1.0/100,000 for girls). In early childhood, a peak incidence of 1.8/100,000 at age 4 yr in boys and 0.9/100,000 at the age 3 yr in girls was noted. The incidence of lymphogranulomatosis seemed to be higher for boys in urban areas and for girls in rural areas; however, the differences were not significant.

2485 EPIDEMIOLOGY OF MALIGNANT TUMOURS WITH SPECIAL REGARDS TO THE OROFACIAL REGION.

(E.) Svejda, J. (Pac. Med., J. E. Purkyne U., Prague, Czechoslovakia) and V. Kosut. *Neoplasma* 22:193-196, 1971.

A survey of cancer incidence statistics compiled in Czechoslovakia since 1959 indicated that the oral cavity and liver were affected twice as often among women as among men in that country. Tumors of the larynx and lungs were more prevalent in males than in females. Tumors of the orofacial region were more common among men than among women; in 1968, there were 676 cases of orofacial cancer among men and 188 among women. "Orofacial tumors" as a nosological entity included tumors of the lip, tongue, salivary glands, base of the oral cavity and other parts of the oral cavity. Of these sites, the most commonly affected was the tongue (6455 cases since 1959) followed by the salivary glands (1084 cases), other parts of the oral cavity (923 cases) and the tongue (825 cases). The incidence of orofacial cancer has declined in Czechoslovakia since 1959; in 1958 orofacial tumors accounted for 3.91% of all tumors and in 1968 they accounted for 2.30% of all tumors. This decline was attributed to improved standards of oral hygiene in Czechoslovakia and to increased availability of dental care. Carcinoma of the lip was found to be more frequent in Czech men than in women and to be twice as common in Slovak regions of the country than in Czech regions. This differential prevalence in the 2 sections of Czechoslovakia was thought to be due to differing climatic and geological conditions and to the different age-structure of the populations of the different regions.

2486 TUMORS OF THE NERVOUS SYSTEM: INCIDENCE AND POPULATION SELECTIVITY. (E.) Leib-

man, U. (Hadassah-Hebrew U. Hosp., Jerusalem, Israel), M. Yablonski and M. Alter. *J Chronic Dis* 10(11):707-721, 1971.

The incidence and distribution of nervous system tumors in the Israeli population during 1961-1965 was studied. A total of 1,354 nervous system tumors were recorded. The annual incidence of these tumors was found to be stable, and the incidence of nervous system tumors ranged from 11.1-14.2 cases/100,000 population. Seventy-six percent of nervous system tumors were situated in the brain; of these 50% were located in the cerebellum. Seven percent of nervous

system tumors affected the spinal cord and 12% affected the peripheral nerves. There were 372 gliomas, 236 meningiomas and 159 neuromas and neurofibromas. The male-female ratio for incidence of gliomas was 1.5 and for meningiomas was 0.6. The total male-female ratio for all nervous system tumors was 1.2. Most nervous system tumors had a higher incidence among European-born Israelis than among Asian-born, African-born or native-born Israelis. Gliomas and pituitary tumors, however, were more frequent among native-born Israelis than among the other 3 groups. Although the mortality and morbidity rates for brain tumors in Israel were well above those for other areas, this excess probably reflects the thoroughness of tumor reporting in Israel rather than a real excess of tumor incidence in that country.

2487 THYROID CARCINOMA IN THE JAPANESE IN

HAWAII. (E.) Fukunaga, F. H. (Kuakini Hosp., Honolulu, Hawaii) and L. J. Lockett. *Arch Path* 92(1):6-13, 1971.

One hundred consecutive autopsies performed on persons of Japanese birth or ancestry in Honolulu disclosed 24 cases of occult thyroid carcinoma; in no case was the thyroid carcinoma the cause of death. Among men, 10 Hawaii-born and 6 Japan-born persons had thyroid carcinomas; among women, 2 Hawaii-born and 6 Japan-born persons had thyroid carcinoma. The finding of 24 thyroid carcinomas in 100 Japanese in Honolulu yielded a prevalence rate for thyroid carcinoma in this population of 24%; the prevalence of thyroid carcinoma among Japanese in Japan who had been exposed to nuclear radiation in the atomic bomb blast of 1945 was 17.8-28.4%. The prevalence of thyroid carcinoma in Philadelphia in a 1969 study was 0.45%. Histological examination of the thyroid carcinomas from the Honolulu group revealed small cell nests resembling parafollicular cells situated between the follicles. It was thought that these cells may have been latent medullary carcinomas.

2488 THE PROBLEM OF GASTRO-INTESTINAL CANCER IN INDIA. (E.) Paymaster, J. C. (Tata

Memorial Centre, Bombay, India) and P. Gangadharan. *The Indian Practitioner* 24(1):7-15, 1971.

Cancer of the esophagus constituted 42% of all gastro-intestinal cancers in India according to records from 24 hospitals reviewed in 1964. It constituted 10% of all malignant neoplasms in males (average age of 53 yr) and 7% in women (average age of 51 yr). The upper third of the esophagus was affected in 20%, the middle third in 55% and the lower third in 25% of cases. The malignant lesions in the upper and middle thirds of the esophagus appeared to be associated with the habit of pan chewing or bidi smoking. Gastric cancer constituted 2% of all malignant neoplasms and 13% of the gastrointestinal tract cancers, with a male to female ratio of 3.4:1; the average age was 55 yr for males and 54 yr for females. Fifty-four percent of these patients had achlorhydria while 5% had hyperacidity. The association between achlorhydria and gastric cancer seemed to pass

through a stage of atrophic gastritis. Ingestion of a considerable amount of smoked or charcoaled food could be ascertained in certain regions with high incidence of gastric cancer. Carcinoma of the rectum affected patients, 32% of whom were below 45 yr of age; the low incidence of colonic cancer in India was attributed to frequent chronic infections with bacillary dysentery, tuberculosis or intestinal parasites, which cause an increased rate of bowel movements. The low incidence of gastric, colonic and rectal neoplasia among the Hindu populations of Gujarat seemed to be associated with their strict vegetarian diet.

2488 CANCER IN SOUTHERN IRAN. (E.) Haghighi, P. (Pahlavi U. Sch. Med., Shiraz, Iran) I. Nabizadeh, S. Asvadi and E. A. Mohallatee. *Cancer* 27(4):965-977, 1971.

The incidence of cancer in the population of Fars Province in Southern Iran during the period 1963-1968 was investigated; 3,295 cases of cancer were diagnosed in the area during this period. The 3 most commonly affected sites among males were skin (15.9% of male cases), digestive organs (16.1% of male cases), and lymphatic and hematopoietic tissues (15.4% of male cases). The 3 most commonly affected sites among females were breast (13.9% of female cases), skin (12.4% of female cases) and cervix (11.0% of female cases). The male:female ratio for cancer incidence at all sites was 1.6:1.0. In females, the 50-55-yr-old age group developed more cancer than any other age group, whereas in males, the most frequently affected age group was the 65-70-yr-old group. Cancer incidence in Fars Province was compared with that in the state of Connecticut, and it was found that cancers of the pharynx, esophagus, stomach, liver, nasal cavities and sinuses, and conjunctiva were more common among younger people in Iran than in Connecticut. The incidence of choriocarcinoma in Fars Province was also markedly higher than in Connecticut.

2489 INTESTINAL METAPLASIA OF GASTRIC MUCOSA IN AUTOPSY MATERIALS IN HIROSHIMA AND YAMAGUCHI DISTRICTS. (E.) Kubo, T. (Fac. Med., Kyushu U., Japan) and T. Imai. *Gann* 62(1):49-53, 1971.

Autopsies were performed on 67 randomly selected subjects from Hiroshima, Japan and on 103 randomly selected subjects from Ube, Yamaguchi Prefecture, Japan to determine the incidence of intestinal metaplasia in these groups; metaplasia was graded from 0 (none) to 3 (many patchy areas of uniform metaplasia). The incidences of metaplasia of various grades in age groups 20-29-yr-old, 30-39-yr-old, 40-49-yr-old, 50-59-yr-old, 60-69-yr-old, 70-79-yr-old and 80-yr-old and over were, resp., 12.5, 33.3, 54.6, 76.5, 87.5, 71.5 and 86.1%. Although metaplasia of grades 2 and 3 was not found in subjects aged 20-39-yr-old, it was found in older subjects, the maximal incidence occurring in the age group 70-yr-old and over (75.8% incidence of the 2 grades). The incidence of intestinal metaplasia in Hiroshima was not significantly

different from that in the Yamaguchi Prefecture; however, the incidence in Hiroshima-Yamaguchi was markedly higher than that in a group of autopsies from Minnesota (the incidence of metaplasia was 25% versus 25% for the 50-59-yr-old age group).

2490 A SURVEY OF ACUTE TOXICITY OF CYCADS AND MORTALITY RATE FROM CANCER IN THE MIYAKO ISLANDS, OKINAWA. (E.) Hirono, I. (Gifu U. Sch. of Med., Japan), H. Kachi and T. Kato. *Acta Paediatr Jap* 29(3):327-337, 1970.

Cancer mortality in the period 1961-1966 was investigated in the population of the Miyako islands (Okinawa); members of this population had subsisted on a diet of cycads for a 3 months period in 1960 when alternative food supplies were damaged by typhoons. Mortality from cancer of various sites among Miyako islanders was compared with mortality in Japan. Records of a total of 1,260 persons subsisting on cycads were examined. The age-adjusted death rate per 100,000 population from stomach cancer among islanders was 28.66, while that among Japanese was 47.02. Stomach cancer mortality was most frequent among persons 69-79-yr-old in the Miyako islands and in Japan. The death rate from hepatoma among islanders was 8.89 deaths/100,000 population, while the hepatoma death rate among Japanese was 8.84 deaths/100,000 population. However, in 2 districts of the Miyako islands the death rate from hepatoma exceeded the hepatoma death rate in Japan. No significant increase in deaths from malignant tumors generally was seen in the Miyako islands during 1961-1966. The death rate from cirrhosis of the liver was higher among the Miyako islanders than among Japanese (18.8 versus 10.10 deaths/100,000 population, resp.).

2491 EPIDEMIOLOGIC CHARACTERISTICS OF CANCER OF THE BREAST IN TAIWAN. (E.) Lin, C. (Coll. Med., Natl. Taiwan U., Taipei), K. P. Chen and B. MacMahon. *Cancer* 27(6):1497-1504, 1971.

The incidence of breast cancer in Taiwan was investigated in interviews with 213 breast cancer cases diagnosed in 1964-1967. The overall age-specific incidence rate in Taiwan for breast cancer was 10.1 cases/100,000 female population; the frequency of breast cancer increased with age until the age of 40 yr, at which time it began to decline. Breast cancer mortality in Taiwan increased steadily with age throughout life. In younger age groups, mortality had an appreciably lower frequency than incidence. Persons who had been born in mainland China had a higher death rate from breast cancer (5.1 cases/100,000) than persons born in Taiwan (3.8 cases/100,000); incidence rates for Taiwanese and mainlanders were 6.5 and 19.7 cases/100,000, respectively. Duration of schooling as an index of socioeconomic status, it was found that persons of high social position had high incidences of breast cancer; however, these differences between high and low socioeconomic position were not statistically significant. Single women were found to have high

incidence rates for breast cancer than married women; the death rate among women 40-49-yr-old was 15.1 for single women and 6.8 for married women. A strong inverse relationship was found between parity and incidence of breast cancer; women who had 2 or more births had 30-40% of the breast cancer risk of nullipara. The association with parity was stronger for older women than for younger women. No clear relationship was seen in Taiwan between incidence of breast cancer and age at first pregnancy; no evidence is forthcoming that breast cancer was influenced by lactation. Although a noticeably high number of breast cancer cases reported menarche prior to age 12 yr, differences in breast cancer incidence among Taiwanese with differing menstrual histories were not statistically significant.

92 ORBITAL TUMOURS IN AFRICAN CHILDREN. (E.) Templeton, A. C. (Dept. Path., Makerere Univ., Kampala, Uganda). *Brit J Ophthalmol* 55(4):254-261, 1971.

Twenty cases of proptosis in children under 16, caused by orbital tumors examined during 1964-1968, were surveyed histologically. Patients consisted of 14 males and 20 females ranging in age between 1 and 15-yr-old. There were 28 cases of Burkitt's lymphoma (equally distributed among the sexes), 8 cases of retinoblastoma, 6 cases of myelocoele, 6 cases of fibrous dysplasia, and 3 cases of pseudotumor. In the patients with chloroma, the peripheral blood was normal in 2 cases but the bone marrow was leukemic in all cases. Although only 1 case of orbital rhabdomyosarcoma was seen, it was known to be common in Uganda. Both nasopharyngeal carcinoma and anterior myelocoele were more common in Nilotic and Sudanese tribes, while Burkitt's lymphoma was more common in tribesmen from north and north-west Uganda. Most chloroma patients were from the Kampala area, a finding which may have represented a selection bias rather than a real geographical preponderance for this condition. Two tumors, retinal anlage tumor and esthesioneuroblastoma were apparently unique to the orbit, and these 2 cases were reviewed in detail.

93 ADULT HODGKIN'S DISEASE IN UGANDA. (E.) Olweny, C. L. M. (Dept. Med., Makerere Univ., Kampala, Uganda), J. L. Ziegler, C. W. Ward and A. C. Templeton. *Cancer* 27(6):1295-1301, 1971.

Case notes on 26 cases of Hodgkin's disease recorded among adults in Uganda were reviewed; the mean age of the patients was 25 yr (range of 6-60 yr), and there were 24 male cases. There were 18 cases of cervical lymphadenopathy and 10 cases of hilar lymphadenopathy; hepatomegaly and splenomegaly were seen in 28 cases. In a prospective study of 18 adult Ugandan Hodgkin's disease patients, the average age of patients was 39 yr and there were 13 males and 5 females. There were 11 cases of cervical lymphadenopathy and 9 cases of hilar lymphadenopathy; marrow, liver, lung and

skin were affected in 17 cases. Fifty percent of the 18 cases were diagnosed as of the mixed cellular histopathological type and 39% were of the lymphocyte depleted type. The more malignant histopathological types of Hodgkin's disease were found to be more common in Uganda than in the United States.

2494 MULTIPLE MYELOMA IN SPOUSES. (E.) Kyle, R. A. (Mayo Clin., Rochester, Minn.), C. W. Heath and P. Carbone. *Arch Intern Med* 127(5):944-946, 1971.

Four couples of which each spouse developed multiple myeloma are described. Individuals ranged in age from 51-72-yr at the time of diagnosis of myeloma. Patients had been married for 6-41 yr at the time of the diagnosis of myeloma, and the interval between the onset of myeloma in one spouse and its onset in the other ranged from 1 month to 15 yr. In all cases, myeloma was diagnosed in the male spouse before it was diagnosed in the female spouse. Six of the patients had increased serum globulin values and 3 showed Bence Jones proteinuria.

2495 CYTOCHEMICAL POPULATION ANALYSIS OF CELL LINES DERIVED FROM BURKITT'S LYMPHOMA, INFECTIOUS MONONUCLEOSIS, AND ACUTE LYMPHOCYTIC LEUKEMIA. (E.) De Bault, L. E. (U. Iowa Coll. Med., Iowa City), G. Gahrton and G. E. Foley. *Exp Cell Res* 65(1):156-160, 1971.

Mean values for dry mass, total nucleotides, and Feulgen-DNA content were determined in cultures of lymphocytic cells from patients with Burkitt's lymphoma, infectious mononucleosis and acute lymphoblastic leukemia. Dry mass values showed a distribution similar to that seen in typical exponential phase cell cultures; the 3 cell populations examined showed similar values for dry mass; mean dry mass values varied from 8.1-9.6 preestablished relative units. Total nucleotide content in the cells was measured by extinction of UV and the values for the 3 cell populations were similar, indicating the relative predominance of DNA over RNA in the cells. The frequency distribution of DNA content in the cells showed a bimodal pattern similar to that exhibited by other exponentially growing cells in culture. The frequency distribution of total dry mass and total nucleic acid content were more variable between cells than would have been expected in normal cell populations.

2496 LIGHT MICROSCOPIC OBSERVATIONS OF MORRIS HEPATOMAS. (E.) Hruban, Z. (Dept. Path., U. Chicago, Ill.), H. P. Morris, Y. Mochizuki, D. R. Meranze and A. Slesers. *Cancer Res* 31(6):752-762, 1971.

Transplantable Morris hepatomas of varying rates of growth were examined under the light microscope to determine whether growth rate correlated with structure. It was found that hepatomas of rapid growth rate (including 3683, 8994 and 9098) were composed of multicellular laminae and had small cells and abundant mitotic figures; these hepatoma cells lacked glycogen and follicles. Hepatomas of intermediate growth rate (including 7316A, 5123A and 9121) were found to contain tubular and follicular structures. Slowly growing hepatomas (including 9A(2G), 9633 and 6) contained laminae formed of a single cell. Correlations were not perfect; many slowly growing hepatomas had some of the structural properties of hepatomas of more rapid growth rates.

- 2497 GROWTH OF LANDSCHUTZ ASCITES TUMOR CELLS IN MICE AND IN NORMAL, IRRADIATED AND PRE-IMMUNIZED RATS. (E.) Reuter, A. M. (Nuclear Energy Study Ctr., Mol, Belgium) and G. Mattelin. *Z Ges Exp Med* 155(2):98-104, 1971.

In normal BALB/c mice inoculated with Landschütz ascites tumor cells, ascites tumors grew exponentially for 9 days after transplantation, whereas tumor growth was exponential for only 3 days in normal Wistar rats inoculated with tumor cells. Tumor growth was determined by counting ascites cells in the inguinal canal of killed mice at various times after transplantation of tumor cells. The number of recovered ascites cells declined steadily from day 1 after transplantation in rats preimmunized with ascites cells; by day 5, 0.1 cell was recovered from immunized mice for each cell initially injected. In irradiated (750 r, whole-body) rats, ascites tumors grew progressively for 7-8 days, and then declined. In the irradiated rats, 30 ascites cells were recovered for each injected cell at day 7, but by day 9, only 3 cells were recovered for each injected cell. When tritium-labeled thymidine was used to label ascites cells injected into mice and rats, the labeled cells were quickly lost in immunized rats; in irradiated rats, the radioactivity in the cells fell off abruptly for 1 day and declined more gradually thereafter. Mice injected with the peritoneal wash of rats injected with ascites tumor cells developed tumors when the rats had been given the ascites cells less than 120 hr prior to the peritoneal wash extraction; after a longer interval in the rats, the peritoneal wash did not give rise to tumors in mice. Ascites cells from rats exposed to irradiation produced tumors in mice even when the cells had been allowed to remain in the rats for 168 hr.

- 2498 REGULATION OF ADENYL CYCLASE IN HEPATOMAS OF DIFFERENT GROWTH RATES. (E.) Allee, D. O. (Indiana U. Sch. Med., Indianapolis), J. Munshower, H. P. Morris and G. Weber. *Cancer Res* 31(5):557-560, 1971.

Normal rat liver, regenerating liver from partial hepatectomized rats, and liver from 6 lines of Morris hepatoma were assayed for adenylyl cyclase activity; the hepatomas included slowly growing strains (9618-B and 7787), tumors of intermediate growth rate (5123-t.c. and 7288-C) and rapidly growing strains (3924-A and 9618-A₂). Adenylyl cyclase activity was measured alone and in the presence of glucagon or sodium fluoride. Adenylyl cyclase activity was similar in normal rat liver and in hepatomas of varying growth rates; enzyme activity range from 0.07-0.14 $\mu\text{mole/g/hr}$ in normal liver and in hepatoma tissue. Enzyme activity in regenerating liver was similar to enzyme activity in sham-operated liver. Addition of sodium fluoride caused an increase in adenylyl cyclase activity to 0.74-1.30 $\mu\text{mole/g/hr}$ in normal and in regenerating livers; sodium fluoride caused similar but smaller increases in tumor tissue enzyme activity. Glucagon stimulation caused a significant rise in adenylyl cyclase activity in normal and in regenerating tissues. In slowly growing hepatomas glucagon increased enzyme activity by 442%, while in hepatomas of intermediate growth, glucagon increased adenylyl cyclase activity by 200%. In the more rapidly growing hepatomas, glucagon increased adenylyl cyclase activity by 138% (not significantly different from unstimulated liver tissue); in one of the rapidly growing hepatomas there was no stimulation of adenylyl cyclase activity by glucagon.

- 2499 CELL PROLIFERATION AND TUMOR GROWTH IN HEPATOMAS 3924A. (E.) Looney, W. B. (Virginia Sch. Med., Charlottesville), A. A. Mayo, M. Y. Janners, J. G. Mellon, P. Allen, D. Salak and H. P. Morris. *Cancer Res* 31(6):821-825, 1971.

Growth characteristics of Morris hepatoma 3924A were investigated, and it was found that the mean cell cycle for this tumor was 28.2 hr and its volume doubling time, 5.5 days. The T_{G1} mitotic phase of Morris hepatoma 3924A was 15 hr in duration, the T_{G2} phase was 3.4 hr, the T_S was 9.4 hr, and the $T_{G1}+T_{G2}+T_S$ was 0.4 hr. Although the potential doubling time of the tumor was calculated to be 42.8 hr, the actual doubling time was 132 hr. The cell loss factor was found to be 0.67 and the growth fraction was 66%. It was found that blood comprised about 0.5% of tumor material; connective tissue comprised about 18%, necrotic tissue comprised about 13%, and tumor tissue comprised about 68%.

00 "SPONTANEOUS" NEOPLASTIC TRANSFORMATION
IN VITRO: THE ULTRASTRUCTURE OF THE
ISSUE CULTURE CELL. (E.) Franks, L. M. (Imperial
Cancer Res. Fund, London, England) and P. D. Wilson.
Cancer J 6(6):517-523, 1970.

The ultrastructures of 11 tumor-producing cell lines
and 13 nonneoplastic cell lines derived from strain
BALB and strain C3H mice were compared; tumor-
producing tissues were taken from kidney, lung,
heart, bladder, tongue and spinal cord and nonneo-
plastic tissues were taken from these organs and
from spleen, prostate and peritoneum. All
exams examined showed 2 predominant cell types:
one cell type had a rounded or bladder-shaped nucleus
with a prominent single nucleolus, the other cell
type had a more convoluted nucleus. Both cell types
were thought to have descended from endothelial
cells and vascular pericytes. Cells in 7 of the 11
tumor-producing cell lines studied had cytoplasmic
lipofuscin deposits; however, there were no consistent
morphological differences between tumor and non-tumor
cells. C-type virus particles were found intra-
cellularly in 7 of 11 tumor-producing lines and in
5 of 13 normal cell lines. Cells from young mice and
from aged mice, cells from different transfer genera-
tions, and cells from different mouse strains were
examined without significant morphological differences.

1 EFFECT OF HYPOTHALAMIC LESIONS ON THE
GENESIS OF SPONTANEOUS MAMMARY GLAND TUMORS
IN THE MOUSE. (E.) Bruni, J. E. (U. Western Ontario
Cancer Res. Ctr., London, Canada) and D. G. Montemurro.
Cancer Res 31(6):854-863, 1971.

Male strain C3D2 F₁ mice were forcebred, and virgin
forcebred mice were subjected to anterior or
middle hypothalamic lesions. A number of the mice
with hypothalamic lesions were rendered sterile.
Among intact forcebred mice, the incidence of mammary
tumors by 60 wk after birth was 93%, whereas the
incidence of mammary tumors among intact virgin mice
at this point was 73%. The latent period for tumor
appearance in intact forcebred mice was 227.5 days,
while the latency for tumors in intact virgins was
344 days. Hypothalamic lesions increased tumor
incidence and reduced tumor latency, although the
effect was not so pronounced as in forcebred mice.
Nulliparous mice given anterior hypothalamic
lesions, the tumor incidence at 60 wk was 100%; in
virgin mice given middle hypothalamic lesions the
incidence was 85%; the tumor latency for
nulliparous mice with anterior lesions was 326 days
while that for virgins with middle lesions was 298.6
days. In forcebred mice with posterior or middle
hypothalamic lesions, the tumor incidence was not
significantly higher than in forcebred mice without
lesions.

INCIDENCE OF SPONTANEOUS TUMORS IN CD^(R)-1
HAM/ICR MICE. (E.) Percy, D. H. (Yale U.
Med., New Haven, Conn.) and A. M. Jonas.
Cancer Inst 46(5):1045-1053, 1971.

The development of spontaneous tumors at various
sites was observed in strain CD^(R)-1 mice in the
following age groups: group I, 0-4 months; group
II, 4-8 months; group III, 8-12 months; group IV,
12-16 months; group V, 16-20 months; and group
VI, over 20 months. The minimal tumor incidence
was seen in group I, in which 2 of 258 mice devel-
oped tumors; the maximal tumor incidence was seen
in group VI, in which 19 of 38 mice developed
tumors. Eighteen of 167 mice in group II developed
tumors, as did 30 of 106 mice in group V. In
groups II, III, IV and V, tumors of the lymphoretic-
ular system were the most commonly developed
lesions. Mammary tumors were most common in groups
III, IV and V, and were relatively uncommon in
group VI; in contrast, pulmonary adenomas were more
common in group VI than in younger age groups (5
pulmonary adenomas in group VI as opposed to 4 in
all other groups). Other tumors developed by the
mice included osteogenic sarcomas, hemangiosarcomas
and renal and hepatic tumors.

2503 TRANSFER RNA AND TRANSFER RNA METHYLATION
IN GROWING AND "RESTING" ADULT AND EMBRYONIC
TISSUES AND IN VARIOUS ONCOGENIC SYSTEMS. (E.)
Gallo, R. C. (Natl. Cancer Inst., Natl. Inst. Hlth.,
Bethesda, Md.). *Cancer Res* 31(5):621-629, 1971.

Escherichia coli tRNA was incubated with leukemic
and normal blast cells, fetal tissue and normal and
neoplastic cell lines for determination of concentra-
tion and activity of tRNA methylase. No significant
differences were found in methylases between the
normal and leukemic lymphoblasts, and both possessed
similar growth rates with virtually identical mor-
phology. When methylases were compared at log phase
vs stationary growth phase, the activities were con-
sistently higher in the cells harvested at log phase
whether normal or neoplastic. Extracts of bone
marrow from normal and chronic myelogenous leukemic
(CML) patients not in an acute phase revealed no
significant differences between normal bone marrow
and leukemic bone marrow extracts when the number of
undifferentiated cells were comparable. However, 2
patients in an acute phase CML and 1 patient with
acute myeloblastic leukemia revealed elevated methyl-
ases. Comparison of peripheral blood of normal donors
and chronic lymphocytic leukemic donors revealed
slightly elevated methylases in the leukemic cells,
but the values were much lower than those found in
normal or leukemic blast cells; a 4- to 7-fold
increase in tRNA methylase activity was seen in
both normal and chronic lymphocytic leukemic cells
in response to phytohemagglutinin.

2504 ISOACCEPTING TRANSFER RNA'S IN MAMMALIAN
DIFFERENTIATED CELLS AND TUMOR TISSUES.
(E.) Yang, W.-K. (Oak Ridge Natl. Lab., Tenn.).
Cancer Res 31(5):639-643, 1971.

Isoaccepting transfer RNA (tRNA) from plasma cell
tumors induced by mineral oil in an inbred strain
of BALB/c mice and reticulocytes from 2 inbred strains

of mice (C57BL/6 and C3H/Anf) were characterized by electrophoretic and chromatographic methods. All aminoacyl-tRNA's derived from tumors producing immunoglobulin A or F were similar in the number and positions of the isoaccepting peaks but were in some cases slightly different in the relative quantities of certain peaks except seryl-tRNA, which showed marked differences. The amino acid composition of reticulocyte hemoglobin α chains of C57BL/6 mouse cells revealed glycine, valine, and asparagine at positions 25, 62 and 68, whereas duplex amino acids (glycine/valine, valine/isoleucine, and asparagine/serine) with a ratio of 30/70 were seen at these positions in the chains from V3H/Anf strain. Reticulocytes from C57BL/6 and C3H/Anf showed identical or similar patterns for tRNA's for glycine, isoleucine, methionine, serine, and tyrosine, but showed a marked difference in valyl-tRNA for which low values were found in the C3H/Anf reticulocytes and high values in the C57BL/6 cells. It is not known whether the characteristic tumor isoaccepting tRNA's are related to the altered methylation of tRNA in tumor tissues.

- 2505 TRANSFER RNA SPECIFICITY IN MAMMALIAN TISSUES AND CODON RESPONSES OF SERYL TRANSFER RNA. (E.) Hatfield, D. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), F. H. Portugal and M. Caicuts. *Cancer Res* 31(5):697-700, 1971.

Transfer RNA was isolated from bovine kidney, liver and brain directly from whole tissue or following the removal of particulate matter, labeled as aminoacyl-tRNA and analyzed by reversed phase chromatography. Differences in methionyl-, arginyl-, and seryl-tRNA elution profiles resulted from fractions from both isolation methods and when compared to profiles from rabbit tissue, the profiles of liver and brain methionyl-tRNA's were comparable; 2 peaks were resolved from arginyl-tRNA of liver compared to 3 peaks from that of rabbit liver. The major differences noted in seryl-tRNA of bovine brain and liver were comparable to those observed in the corresponding rabbit tissues. These differences, also seen in chicken tissue, did not appear to be affected by heating brain and liver at elevated temperatures in the presence or absence of magnesium. Peak I of liver and Peaks I and II of brain responded to AGU and AGC serine codons; Peak II of liver and Peak III of brain responded to UCG; Peak III of liver and Peaks IV and V of brain responded to UCU, UCA and UCC.

- 2506 THE REGULATION OF TRANSFER RNA METHYLATION IN NORMAL AND NEOPLASTIC MAMMARY CELLS. (E.) Turkington, R. W. (Duke U. Med. Ctr., Durham, N. C.). *Cancer Res* 31(5):644-646, 1971.

The activities of 6 base-specific methylating enzymes were assayed in C3H mouse midpregnancy mammary epithelial cells incubated in organ culture on medium containing insulin. Each of these enzymes increases during the developmental period to maintain character-

istic relative activities, and each was induced by insulin in organ culture. A partially synchronous wave of DNA synthesis was observed following increase in the cellular content of tRNA during the G₁ phase in these epithelial cells. Comparisons of these methylases with those found in spontaneous and serially transplanted mammary carcinomas showed that the specific activity of total tRNA methylase is higher in neoplastic than in normal cells without the corresponding increase in the intracellular content of tRNA; this increase involved a marked increase in some enzymes, such as uridine 5-methylase, while other enzymes were not altered. This distortion of the characteristic enzyme profile was associated with the appearance of tRNA guanine 7-methylase, which was not found in normal C3H mouse mammary tissue. The most attractive explanation for the presence of guanine 7-methylase in the neoplastic mammary epithelial cells is that the gene(s) for this enzyme is normally repressed but becomes activated as a consequence of the neoplastic transformation.

- 2507 IN VITRO TRANSFER RNA METHYLATION IN PAIRED NEOPLASTIC AND NONNEOPLASTIC CELL CULTURES. (E.) Gantt, R. R. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Cancer Res* 31(5):609-612, 1971.

A paired cell line, in which a malignant line was derived from the nonmalignant line, was initiated from a minced mouse embryo pool and was serially cultured in suitable media; both cell lines were labeled with methionine and were assayed for tRNA methylase activity. Radioactive profiles in reversed phase chromatography indicated that the labeled methyl group distribution was quite similar in the malignant and nonmalignant tRNAs. However, in one area of the radioactivity profile relationship more methylation of the malignant cell tRNA was noted. Results were confirmed by Dowex 1-formate column chromatography of the hydrolyzed tRNA's which indicated that 2 extra components were contributed by the malignant cell tRNA. Results are consistent with the aberrant methylation hypothesis of neoplasia advanced by other workers.

- 2508 ANALYSIS OF 5-METHYLURIDINE FUNCTION IN THE TRANSFER RNA OF *ESCHERICHIA COLI*. (E.) Björk, G. R. (Dept. Biol. Sciences, Purdue Univ., Lafayette, Ind.) and F. C. Neidhardt. *Cancer Res* 31(5):706-709, 1971.

Induced mutational defects in genes controlling specific methylation activities were used to compare isogenic pairs of methylation-defective and nondefective strains of *Escherichia coli* mutants to compare growth rate, polypeptide chain growth rate, cell size, and macromolecule composition as well as the relative activity of selected enzymes. Analysis of RNA that was methylated revealed that 6 mutants accepted methyl groups *in vitro* into tRNA, 3 accepted them into rRNA, and 1 accepted them into both. Those accepting methyl groups into tRNA only lacked 5-methyluridine to different degrees in the tRNA, and the mutants

accepting methyl groups into rRNA did so by forming 2-methylguanosine; the mutant accepting methyl groups into both was shown to be a double mutant lacking 1-methylguanosine in its rRNA and 5-methyluridine in its tRNA. Three mutants accepting methyl groups solely into tRNA were shown to possess a gene between minutes 77 and 82 on the *E. coli* chromosome *trmA*. Growth rates of transductant pairs with a *trmA4* allele caused a 15% reduction in a rich medium and a succinate-minimal medium and a 7% reduction in glucose-minimal medium with no observable reduction in a glycerol-minimal medium. Introduction of the *trmA5* gene into various *E. coli* strains caused the same pattern of growth rate changes, yet failed to effect change in yet another strain.

509 COMPARATIVE TRANSFER RNA METHYLASE CAPACITY IN MOUSE ASCITES TUMORS AND IN THEIR DERIVED TUMORIGENIC AND NONTUMORIGENIC CELL CULTURES. (E.) Dell'Orco, R. T. (Dept. Cancer Res., U. Saskatchewan, Saskatoon, Canada), D. G. R. Blair and J. F. Morgan. *Cancer Res* 31(5):561-565, 1971.

Mouse ascites tumor cells of 2 types (TA3 adenocarcinoma and 6C3HED lymphosarcoma) and tumorigenic and nontumorigenic cultured mouse cells were tested for their ability to methylate transfer RNA (tRNA) of *Escherichia coli* B. The nontumorigenic mouse cells were unable to induce tumors in mice after passage in culture. Cells of the 2 ascites tumors showed different capacities to methylate *E. coli* tRNA; the ascites cells designated TA3 had a 30% greater methylating capacity than did the cells designated 6C3HED. Cell extracts from 9 day TA3 ascites tumors and from TA3 tumorigenic cultured cells showed 50-60% more methylating ability than did extracts from nontumorigenic cultured mouse cells of the same cell line. However, 9-day 6C3HED ascites cell extracts showed no difference in tRNA methylase activity when compared to extracts from 6C3HED nontumorigenic cultured cells. Evidently loss of tumorigenicity in this ascites cell system does not entail altered tRNA methylase activity. In a related experiment, it was found that the tRNA methylase activity of cells from a solid 3-methylcholanthrene-induced tumor in mice was 35% greater than that of normal mouse liver and 80% greater than that of normal mouse lung cells.

510 TRYPTOPHANYL TRANSFER RNA SYNTHETASE FROM LYMPHOCYTES OF HUMAN CHRONIC LYMPHOCYTIC LEUKEMIA. (E.) Tchou, H. P. (U. Miami Sch. Med., Fla.), A. J. Claflin and K. H. Muench. *Cancer Res* 31(5):679-683, 1971.

Purification of tryptophanyl tRNA synthetase from a lymphocyte-rich fraction of peripheral blood of a single patient with chronic lymphocytic leukemia was achieved by column chromatography followed by isoelectric focusing, which revealed an isoelectric point of 5.2-5.3. The enzyme was stable in potassium and sodium phosphate buffers at pH 6.9 in the presence of glycerol and 2-mercaptoethanol at 0° and retained 50% of its original activity after 17 days. Phosphate

buffer inhibited enzymatic activity at 100 mM; optimum ATP concentration was 1-3 mM. The enzyme sedimented as a single, symmetrical peak in sucrose density gradient centrifugation and had a molecular weight of about 90,000.

2511 AGENTS OF MODULATION OF THE TRANSFER RNA METHYLASES. (E.) Kerr, S. J. (U. Colorado Med. Ctr., Denver), O. K. Sharma and E. Borek. *Cancer Res* 31(5):633-636, 1971.

The role of regulatory agents on tRNA methylase activity is discussed. An inhibitor fractionated from extracts of adult mammalian tissues by column chromatography on Sephadex G-25 revealed inhibitory action only when the peak fractions I and II were combined. These were a high-molecular weight fraction, sensitive to trypsin and to heating at 100° for 1 min and a low-molecular weight component, which was not inactivated by heating for 10 min at 100°. Embryonic tissue, a Novikoff hepatoma, a Morris hepatoma and Ehrlich ascites cells were found to contain only the low molecular-weight inhibitor component. Ovariectomy reduced the tRNA methylase capacity in extracts of uteri of ovariectomized animals compared with extracts of uteri of intact animals, and the administration of physiological levels of estradiol *in vivo* restored the tRNA methylase capacity; these results were interpreted as an indication of hormonal regulation of the tRNA methylase inhibitor.

2512 TRANSFER RNA METHYLASE ACTIVITY IN NORMAL RAT LIVER AND SOME MORRIS HEPATOMAS. (E.) Sheid, B. (Dept. Pharmacol., State U. New York, Downstate Med. Ctr., Brooklyn), S. M. Wilson and H. P. Morris. *Cancer Res* 31(6):774-777, 1971.

Six Morris hepatomas were transplanted every 4-16 wk into Buffalo male and female rats and the resultant tissue growths were assayed for tRNA methylase activity. All of the 6 Morris hepatomas revealed higher tRNA methylase activity than liver derived from either normal or tumor-bearing animals, the latter two showing no difference. This increased activity corresponded to the growth rates but not in linear fashion. The overall patterns of tRNA methylation produced by the hepatomas and normal liver appeared to be similar, indicating that increased methylase activity may merely reflect an increase in the overall synthesis of RNA by the tumors.

2513 STUDIES ON SYNTHESIS AND MODIFICATION OF TRANSFER RNA. (E.) Gefter, M. L. (Dept. Biol. Sciences, Columbia U., New York, N. Y.) and E. Bikoff. *Cancer Res* 31(5):667-670, 1971.

Escherichia coli was infected with bacteriophage $\phi 80\text{psuIII}$ into which was incorporated the structural gene for tRNA^{tyr}₄^G. Following infection there was a 7-15-fold net increase in tyrosine tRNA; the

majority of tRNA^{Tyr} synthesized was deficient in 2-methylthio-N⁶-(γ,γ -dimethylallyl)adenosine. Reverse-phase column chromatography revealed that, in the order of elution of the unmodified RNA, Peak I contained adenosine adjacent to the anticodon, Peak II, N⁶-(γ,γ -dimethylallyl)adenosine, and Peak IV, 2-methylthio-N⁶-(γ,γ -dimethylallyl)adenosine. The unmodified RNA functioned in protein synthesis with about a 10% efficiency relative to the fully modified RNA. The interpretation of results is complicated by the fact that the effect of a base sequence change cannot be separated from a structure change.

- 2514 THE ANALYSIS OF MALIGNANCY BY CELL FUSION: II. HYBRIDS BETWEEN EHRlich CELLS AND NORMAL DIPLOID CELLS. (E.) Bregula, U. (Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), G. Klein and H. Harris. *J Cell Sci* 8(3):673-680, 1971.

Hybrid cell lines were established by fusing Ehrlich ascites tumor cells taken from the peritoneal cavity of mice with fibroblasts obtained from CBA mouse embryos bearing the T6T6 chromosomal translocation. The tumorigenicity of these hybrids was observed in newborn CBA mice which had been exposed to 400 rads of X-irradiation. All hybrid populations were highly tumorigenic; none of the hybrid clones showed a tumor take incidence of less than 60% when inoculated into mice. Although the modal chromosome number to be expected in a hybrid cell line resulting from the fusion of a modal Ehrlich cell with a fibroblast would be 116, the Ehrlich/fibroblast cells had chromosome numbers which fell short of this number by 15-25 chromosomes. Hybrid cells with chromosome numbers approximating the sum of the numbers of both parent cells could not be obtained. The T6 translocation was the only marker chromosome detectable in the Ehrlich/fibroblast hybrids; nevertheless, it seemed likely that at least some of the lost chromosomes in the hybrids were fibroblast chromosomes. In some cases, the chromosome number of cells of tumors produced by the Ehrlich/fibroblast hybrids were similar to those of the hybrid cells themselves, while in other cases, tumor cells showed a reduced modal chromosome number. All tumors showed progressive reduction in chromosome number on transplantation *in vivo*.

- 2515 HUMAN LEUKEMIC CELLS: INHIBITORY EFFECTS OF ISOLOGOUS AND HOMOLOGOUS HISTONES. (E.) Desai, L. S. (Harvard Med. Sch., Boston, Mass.) and G. E. Foley. *Exp Cell Res* 66(1):1-4, 1971.

The effect of histones isolated from the blood of 2 pediatric patients with acute lymphoblastic leukemia, from the blood of a pediatric patient with infectious mononucleosis, and from the bone marrow of a normal pediatric patient on RNA synthesis in normal human fibroblasts *in vitro* was assessed. RNA synthesis was measured by the uptake of ³H-6-uridine by fibroblasts. Histones from the normal patient and from one of the leukemic patients failed to affect ³H-6-

uridine incorporation into the fibroblasts, but histones from the other leukemic patient and from mononucleosis patient produced drastic inhibition of uridine uptake. Untreated fibroblasts had incorporated 1400 cpm/mg RNA of uridine by 18 hr in culture, whereas fibroblasts treated with histones from one of the leukemic patients or from the mononucleosis patient had each incorporated less than 500 cpm/mg RNA of uridine at 18 hr. Histones from the leukemic patient inhibited RNA synthesis in isologous cells to a greater degree than did histones from cells of the mononucleosis patient. Histones from all donors were found to have similar amino acid composition.

- 2516 CYTOPHOTOMETRIC DETERMINATIONS OF DNA CONTENTS IN PRIMARY TUMORS AND METASTASES. (Ger.) Zank, M. (Path. Inst. Karl Marx U., Leipzig, Germany) and H. Krug. *Arch Geschwulstforsch* 36(4):343-351, 1970.

Cell nuclei from primary tumors and metastases were examined for DNA contents using a scanning recording cytophotometer; material included malignancies of the colon, stomach, prostate, bronchi and larynx obtained within 24 hr post-mortem from 10 patients. The karyograms of the primary tumors were categorized under 3 groups according to the frequency distribution of DNA contents of the single cell nuclei, with no correlation between site, cell morphology or logical features was found. Significant differences in average relative values of DNA levels were found between cell nuclei of primary tumor and metastases in 4 out of 10 carcinomas; DNA levels appeared to be higher in the metastasis of colon and prostate carcinoma (27 and 30 U) than in the primary tumor (23 and 23 U, resp.) and were higher in the primary tumor of the gastric and rectal carcinoma (26 and 28 U) than in the metastasis (16 and 22 U, resp.). These data were reflected in corresponding differences in frequency distributions of DNA levels of the individual cell nuclei. The distinct frequency peak in DNA distribution and of its double values characteristic for the major part of the investigated tumors confirmed the Makino and Sandritter lineage theory of tumor development; these peaks should be considered as DNA-stem lines.

- 2517 ISOLATION AND CHARACTERIZATION OF RNA FROM LYMPHOCYTES OF CHRONIC LYMPHOCYTIC LEUKAEMIA. (E.) Deutsch, A. (Chemical Centre, Uppsala, Sweden) and A. Norden. *Scand J Haemat* 8(2):112-117, 1971.

RNA was isolated from lymphocytes with different responses to phytohemagglutinin from chronic lymphocytic leukemia (CLL) patients. The total content of RNA amounted to 0.2-0.3 mg/10⁸ cells. Most of the RNA was obtained in the first extraction step at pH 7.6, and 5-20% was extracted at pH 9 and 60°C. Centrifugation patterns of RNA from the pH 7.6 extracts from lymphocytes of CLL patients were the same as those from normal subjects (28S, 18S and 4S) in 4 of 11 cases. In the other investigated cases of CLL, gradient profiles were obtained which were

acterized by the presence of large amounts of relatively low molecular weight material or of heterogeneous material spreading over the whole range of 28S-4S region. Gel chromatography, gel electrophoresis and sodium chloride fractionation confirmed gradient centrifugation results; RNA from lymphomas that did not respond to phytohemagglutinin resembled normal lymphocyte and liver RNA, while CLL lymphocytes that responded to phytohemagglutinin gave patterns characterized by smaller proportions of 18S components and larger amounts of either relatively low molecular weight material or of polymeric material (28S-4S).

MODIFIED BASES AND TRANSFER RNA FUNCTION.

(E.) Peterkofsky, A. (Nat'l. Heart Lung Inst., Nat'l. Inst. Hlth., Bethesda, Md.), M. Litman and J. Marmor. *Cancer Res* 31(5):675-678, 1971.

Methyl-deficient tRNAs prepared from *E. coli* were compared to tRNA extracted from organisms grown under normal amino acid-supplemented conditions. A comparison of the elution patterns of methyl-deficient tRNA fully acylated with methionine and same tRNA acylated to only a small extent showed significant differences. The deficient species presented a different codon recognition pattern from normal leucine-tRNA, which was bound to ribosomes equally well in response to copolymers containing either uridine and cytosine or uridine and guanine; deficient species responded much better to the uridine-cytosine polymer. The special initiation functions of formylmethionine tRNA were unchanged by lack of methylated bases.

CHROMOSOMAL PATTERNS IN HUMAN MENINGIOMAS.

(E.) Mark, J. (Inst. Pathology, U. Lund, Sweden). *Europ J Cancer* 6(6):489-498, 1970.

Chromosomal studies were carried out on 12 benign meningiomas; case material was drawn from 12 patients 14-68-yr-old and consisted of predominantly cytological and transitional tumors located in the falx, olfactory groove, in the parietal regions (6 cases), and elsewhere. Most tumors were hypodiploid; the modal chromosome peak was 45. In 75% of the tumors, there were numerical and/or structural aberrations of the G group of chromosomes. About 50% of the tumor cells showed marker chromosomes. Chromosomes C and G were primarily involved in the formation of marker chromosomes; in some cases, marker chromosomes were hidden in C chromosomes and did not appear overtly. It was found that in a group of malignant primary tumors in children the major chromosomal aberrations were found in the G and C groups, as they were in the meningiomas.

PATTERNS OF ISOACCEPTING PHENYLALANINE TRANSFER RNA IN HUMAN LEUKEMIA AND LYMPHOMA.

(E.) Mittelman, A. (Roswell Park Memorial Inst., Buffalo, N.Y.). *Cancer Res* 31(5):647-650, 1971.

Transfer RNA^{Phe} was extracted from fresh, surgically removed spleens from patients with leukemia, malignant lymphomas, and nonneoplastic disease and aminoacyl tRNA synthetase was extracted from spleen and human fetal liver; the tRNA and synthetase were used for assay of amino acid acceptor activity. Attempts to charge tRNA extracted from 3 spleens with a number of amino acids were not successful until the RNA was run through BD-cellulose chromatography. Nonneoplastic spleen accepted RNA^{Phe} only. Transfer RNA extracted from both neoplastic and nonneoplastic spleen exhibited similarities in the pattern of phenylalanine tRNA separation and charging; 2 well-defined phenylalanine-accepting peaks were seen when autologous aminoacyl synthetases were used, and a third isoaccepting tRNA^{Phe}, not previously reported, was found in malignant lymphomas and chronic lymphatic and myelogenous leukemias.

2521 RESPONSE OF MODIFIED PHENYLALANINE TRANSFER RNA TO RECOGNITION BY PHENYLALANINE TRANSFER RNA SYNTHETASE. (E.) Stulberg, M. P. (Oak Ridge Nat'l. Lab., Tenn.) and L. R. Shugart. *Cancer Res* 31(5):671-674, 1971.

Undermethylated *Escherichia coli* tRNA^{Phe} prepared by reversed-phase fractionation was measured for activity and phenylalanine acceptance. Preparation 1 (original) had reduced activity for total phenylalanine acceptance and was highly methylated whereas Preparation 2 (purified from same batch as preparation 1 several yrs and several columns later) as well as preparation 3 (from a new growth of cells) showed significantly reduced activity with the undermethylated preparations demonstrating equal initial velocities at saturating tRNA^{Phe} concentrations. Optical rotatory dispersion spectra of undermethylated and normal tRNA showed great similarity but there was a noticeable divergence in the lower wavelength region in the undermethylated fraction; circular dichroism spectra indicate a deviation from the normal on the rising limb of its absorption curve. Hyperchromicity changes at 260 nm with increasing temperature showed that the undermethylated sample began melting out at the same temperature as the normal preparation but soon deviated from this curve and showed an increased rate of melting out at lower temperatures. Phenylalanine incorporation in response to poly U-stimulation was markedly reduced in the undermethylated fraction.

2522 EFFECT OF SEX ON THE DEVELOPMENT OF MELANOMA IN HYBRID FISH OF THE GENUS *XIPHOPHORUS*. (E.) Siciliano, M. J. (Biol. Dept., Long Island U., Brooklyn, N. Y.), A. Perlmutter and E. Clark. *Cancer Res* 31(6):725-729, 1971.

The incidence of melanoma development was observed in the offspring of matings between the platyfish (*Xiphophorus maculatus*) and the swordtail fish (*Xiphophorus helleri strigatus*); matings were effected by artificial insemination. In some cases

the female partner to the cross was a platyfish, and in some cases a swordtail. Of male offspring of a female platy x male swordtail cross, 88% developed melanoma; the percentage of female offspring of this cross developing melanoma was 55.9%; among offspring of a female swordtail x male platy cross, 78% of the males and 51.6% of the females developed melanomas. By 300 days after birth, 85% of all males had melanoma and 53% of all females had melanoma. The tendency for a higher percentage of males to develop melanoma existed in F_1 generation fish from the female swordtail x male platy cross as well as in the F_1 generation of the reciprocal cross. It was thought that the excess of tumor development among male fish was due to an augmentation of melanotic process by the male sex hormones.

- 2523 TRANSFER RNA AND TRANSFER RNA METHYLASE IN HUMAN BRAIN TUMORS. (E.) Viale, G. L. (Neurosurgical Clin. U. Genoa, Italy). *Cancer Res* 31(5):605-608, 1971.

Tissue from 68 human brain tumors and 6 normal human brains were used for preparation of tRNA and were assayed for methylase capacity. Tumor tissue methylated tRNA 3-4 times more actively than normal tissue irrespective of the type of neoplasm which was the source of the methylases of the tRNA; tumor tissues also contained larger amounts of methylated nucleosides than those from normal brain tissue. Rapidity of growth did not correlate with methylase activity or capacity. Sequential methylation of homologous substrates suggest that a shift in the specificity occurs in tumor material.

- 2524 CHROMOSOME NUMBER ADJUSTMENT IN THE LANDSCHÜTZ MOUSE ASCITES CANCER. (E.) Leonard, A. (Dept. Radiobiol., C.E.N.-S.C.K., Mol, Belgium). *Rev Europ Etud Clin Biol* 16(1):58-61, 1971.

After 7-900 transplantation passages, karyotype studies were performed on cells of a mouse Landschütz ascites tumor. This tumor has a stable stem line of 46 chromosomes and contains 3 minute acrocentrics, 1 having a secondary constriction; the 46th chromosome is a long metacentric. Karyotype studies on passaged Landschütz cells from mice which had been given an i.p. injection of 0.5 cc of an 0.025% colchicine solution showed that the stemline chromosome number had changed from 46 to 44. One of the minute acrocentrics had disappeared; however, the long metacentric and the acrocentric with the secondary constriction were still in evidence.

- 2525 THE CHROMOSOMAL ABERRATION OF DOUBLE-MINUTES IN A HUMAN EMBRYONIC RHABDOMYOSARCOMA. (E.) Granberg, I. (U. Hosp. Inst. of Pathology, U. Lund, Sweden) and J. Mark. *Acta Cytol* 15(1):42-45, 1971.

Biopsy material was collected from an embryonic rhabdomyosarcoma which arose in a 16-yr-old boy; the tumor had been exposed to radiation. Chromosome studies showed that the tumor had a hypotriploid cell stemline. All cells examined contained double-minute chromosomes, the number of double-minutes varying from 3-60/cell. Most cells had less than 10 double-minute chromosomes. Interphase cells showed a relatively high number of micronuclei, suggesting that the double-minute chromosomes behaved irreversibly in mitosis.

- 2526 TRANSFER RNA MODIFICATIONS AND SYNTHESIS IN ANIMAL CELLS. (E.) Taylor, M. (Dept. Microbiol., Indiana U., Bloomington), S. Volkers, B. K. Choe and J. G. Zeikus. *Cancer Res* 31(5):688-693, 1971.

Alterations in chromatographic patterns of specific species of tRNA's have been studied in sea urchin from the time of fertilization to the formation of the late mesenchyme blastula by means of column chromatography of 8 different aminoacyl-tRNA's in unfertilized eggs and mesenchyme blastula and in Morris hepatomas. No elution differences could be found for arginyl-, tyrosyl-, valyl-, phenylalanyl-, aspartyl-tRNA but repeated differences were found chromatographically for leucyl-, seryl-, and lysyl-tRNA. These data suggest that certain species of blastula tRNA's differ from egg tRNA, which must result from modifications of existing tRNA's. Regenerating rat liver and normal rat liver, used as comparisons, demonstrated no detectable differences in reverse phase partition chromatography. However, with 2 hepatomas, classified as highly differentiated and well-differentiated, resp., distinct repeatable differences were found in seryl-, prolyl-, alanyl-, histidyl-, and lysyl-tRNA's but no differences were detectable between a poorly differentiated hepatoma and regenerating rat liver.

- 2527 APPLICATION OF A TRITIUM DERIVATIVE TO HUMAN BRAIN AND BRAIN TUMOR TRANSFER RNA ANALYSIS. (E.) Randerath, K. (Massachusetts General Hosp., Boston). *Cancer Res* 31(5):658-661, 1971.

Unfractionated tRNA isolated from various normal and neoplastic tissues were analyzed for base composition by means of a tritium derivative method. Substantial changes of the minor base composition were found in tumor tRNA when compared to tRNA isolated from normal human brain tissue. There was a slightly higher level of 7-methylguanosine in glioblastoma multiforme than in normal brain tissue. Values for brain tissue resemble reported values for rat liver.

- 2528 MITOCHONDRIAL RIBOSOMES IN HeLa CELLS. (E.) Attardi, G. (California Inst. of Technology, Pasadena) and D. Ojala. *Nature* 229(5):133-136, 1971.

sedimentation properties of the submitochondrial fractions obtained from Triton X-100 lysates of mitochondria from HeLa cells that had been exposed for 2 hr to ^3H -5-uridine in the presence of 0.1 $\mu\text{g/ml}$ actinomycin D were investigated. The A_{260} profile of the sedimentation pattern showed 3 radioactive peaks, 60S, 45S and 35S, as well as an unlabeled 74S peak. The RNA extracted from the peak fraction of the 60S component showed both 16S and 12S species; the RNA from the peak fraction of the 45S peak showed principally a 16S component and some 12S, whereas RNA from the peak fraction of the 35S peak showed mainly a 12S component. These radioactive peaks appear to represent mitochondria-specific mononucleoprotein particles containing 16S and 12S RNA. Reconstruction experiments using purified 12S and 16S RNA with unlabeled mitochondrial suspensions produced no discrete 35S, 45S or 60S peaks from artificial complexing with proteins. That the 60S particles represent mitochondria-specific ribosomes is supported by the inhibition of its synthesis by chloramphenicol and its insensitivity to cycloheximide. The 45S and 35S particles are probably subunits of the 60S ribosomes.

9 ENGAGEMENT OF CYTOPLASMIC POLYRIBOSOMES IN THE SYNTHESIS OF RIBOSOMAL PROTEINS IN EUCARYOTIC CELLS. (E.) Chiarugi, V. P. (Inst. Biol. Path., U. Florence, Italy). *Cancer Res* 31(6): 1185-1190, 1971.

^3H -labeled structural ribosomal proteins were extracted from mouse Ehrlich adenocarcinoma ascites cells and ^3H -labeled proteins were produced by a cell-free system of cytoplasmic polyribosomes. Labeled proteins were subjected to electrophoresis on polyacrylamide gels. C^{14} -labeled ribosomal proteins and ^3H -labeled peptide chains were found to produce congruent electrophoretic patterns among the fast-moving proteins, but the 2 proteins did not show congruent electrophoretic patterns among the slower fractions. When the 2 proteins were examined by carboxymethylcellulose chromatography, both proteins eluted at approximately the same positions. Apparently, a cell-free system from the Ehrlich ascites cells is able to synthesize some proteins which behave chromatographically and electrophoretically as ribosomal proteins.

80 HUMAN LEUKEMIC CELLS: ABNORMAL AMOUNT OF METHYLATED BASE IN DNA. (E.) Desai, L. S. (Harvard Med. Sch., Boston, Mass.), U. C. Wulff and E. Foley. *Exp Cell Res* 65(1):260-263, 1971.

Base ratio and nearest neighbor analyses were determined with DNA isolated from cultures of human leukemic lymphocytes. The hydrolysates of DNA from human lymphocytic cells exhibited patterns similar to those of leukemic lymphocytes with respect to major deoxyribonucleotides, although there seemed to be minor differences in base content, particularly in thymine and guanine. ^3H -L-Methionine-methyl was incorporated primarily into thymine and cytosine, and to a lesser extent, into guanine. An extra small peak which mi-

grated between cytosine and thymine and which had an R_f value identical with that of 5-methylcytosine was seen in DNA derived from patients with leukemia but not in DNA from cells derived from patients with infectious mononucleosis or in normal lymphocytic cells. This distinction between lymphocytes of leukemic and infectious mononucleosis patients, as well as other reported metabolic differences, suggests functional and/or regulatory differences between the lymphocytes which may relate to the manifest biological differences between these 2 lymphoproliferative diseases.

2531 PRIMARY POLYCYTHAEMIA: CORRELATIONS BETWEEN THE HISTOLOGIC APPEARANCES AND THE CHROMOSOME PATTERN OF THE BONE MARROW CELLS DURING THE DISEASE. (E.) Visfeldt, J. (Community Hosp., Copenhagen, Denmark), S. Franzen and B. Tribukait. *Acta Radiol* 10(1):86-114, 1971.

Bone marrow cells and peripheral blood cells from 25 patients with polycythemia were subjected to karyotype studies; patients ranged in age from 22-74 yr and were classified as untreated (4 patients), treated and without bone marrow fibrosis (9 patients), treated and with bone marrow fibrosis (5 patients), and treated and showing incipient transition to leukemia (7 patients). Treated patients had often received radiation. Unstable chromosome aberrations were found mainly in peripheral blood of these patients and consisted chiefly of dicentrics, rings and acentric fragments. No tracentrics were seen and no significant increase in chromatid aberrations was seen in the patients. Most aberrations were explained as deletions. The maximum incidence of aberrations was 91% in treated patients without myelofibrosis, 100% in treated patients with myelofibrosis, 100% in patients with incipient leukemia and 9% in untreated patients. Clone formations were seen in bone marrow specimens from 12 patients.

2532 CYTOLOGICAL AND CYTOGENETICAL STUDIES ON BRAIN TUMORS: III. Ph^1 -LIKE CHROMOSOMES IN HUMAN MENINGIOMAS. (E.) Zankl, H. (Max-Planck Inst. Psychiatry, Munich, Germany) and K. D. Zang. *Humangenetik* 12(1):42-49, 1971.

A survey of 70 human meningiomas revealed 5 having a chromosome resembling the Philadelphia chromosome (Ph^1) previously associated with chronic myelogenous leukemia. Three of the meningiomas were arachnoid, 1 was endotheliomatous and 1 was fibromatous. In 3 tumors having a modal chromosome number of 46 the Ph^1 chromosome could be shown to be a deleted G chromosome, while in the other 2 meningiomas it was suspected but not shown that the G group was the origin of the Ph^1 .

2533 CANCER FAMILY "G" REVISITED: 1895-1970. (E.) Lynch, H. T. (Creighton U. Sch. Med., Omaha, Nebr.) and A. J. Krush. *Cancer* 27(6):1505-1511, 1971.

The incidence of cancer was investigated in members of a family which was seen to have a high frequency of cancer cases when first examined in 1895. The family's "progenitor" had 10 children, of whom 6 developed carcinoma; the descendants of the 10 children were taken as unit groups, and it was found that 8 of the 10 groups were cancer-prone. Investigation of the branches of the family ultimately involved 650 related individuals. In these 650, there were 95 cases of cancer; in the 8 cancer-prone branches of the family, the cancer incidence ranged from 20-62%. Stomach cancer, colonic cancer and endometrial cancer tended to cluster in cancer-prone families, as did leukemia and lymphosarcoma. The sex ratio of males to females in the family who had been affected by cancer approached 1:1.

- 2534 FANCONI'S ANAEMIA IN THE GENETICS OF NEOPLASIA. (E.) Swift, M. (New York U. Med. Ctr., New York). *Nature* 230(5293):370-373, 1971.

Genetic studies in patients with Fanconi's anemia (FA) from 8 families were performed. Lymphocyte cultures from the living probands (belonging to 5 of these families) and cultures previously prepared from a proband who died later showed the specific characteristic chromosomal features. In one of the 8 families the parents were first cousins. Since 1930, 102 deaths of relatives whose prior probability of FA heterozygosity was higher than 0.1 occurred. Malignant neoplasm was the cause of death in 27 cases, and the age of death ranged between 50 and 74 yr. In a normal population 17 deaths from malignant neoplasm would be expected under similar distribution by age and year of death (1952). Of the malignant neoplasms which occurred in the 8 families excluding the probands (372 living relatives), several types of neoplasia occurred with unusually high frequency. Three cases of leukemia were found where 1 would be expected. Two of these cases were in 1 family, acute myeloblastic leukemia in an uncle and acute lymphatic leukemia in a first cousin of an FA proband. There were 5 colonic and 4 gastric carcinomas, while in a normal population perhaps 2 of each would have occurred in 102 deaths. Since it is not possible to distinguish FA heterozygotes from non-carriers in the FA families, there was no way to tell from these data whether specific types of cancer or leukemia were associated with the FA gene. There are no precise estimates of the incidence of FA homozygotes or of the frequency of the FA gene. However, if the FA heterozygotes are about 3 times as likely as non-carriers to die from a malignant neoplasm, (as the data indicate) then they would constitute 1% of all patients dying of cancer or leukemia.

- 2535 TESTICULAR MORPHOLOGY AND GERM CELL DNA SYNTHESIS IN THE TESTIS OF PATIENTS WITH PROSTATIC CARCINOMA. (E.) Markewitz, M. (Francis Delafield Hosp., New York, N.Y.), R. J. Veenema, B. Fingerhut and E. Gursel. *Cancer* 27(4):919-924, 1971.

In biopsy studies of testicular tissue taken from 175 patients with histologically proven carcinoma

of the prostate, it was found that 40-45% of biopsied testicular tissues contained seminiferous tubules with full and satisfactory spermatogenesis. In 35-40%, spermatogenesis was active but depleted. Leydig cells were increased in this second group. In the remaining 20-25%, atrophy and hyalinization were seen. DNA synthesis was found to be reduced in all 3 groups of testicular biopsies from carcinoma patients. No consistent correlation could be found between testicular morphology, DNA synthesis and serum testosterone levels in the patients.

- 2536 MODAL DNA VALUE AND CHROMOSOME NUMBER IN OVARIAN NEOPLASIA. (E.) Atkin, N. B. (Mount Vernon Hosp., Northwood, Middlesex, England). *Cancer* 27(5):1064-1073, 1971.

Chromosome preparations were made from tissue of patients with ovarian carcinoma for modal value and DNA content determination by means of microspectrophotometry. The carcinomas appeared to fall into discrete groups according to their modal chromosome numbers, whether assessed from metaphase chromosome counts or DNA measurements on interphase cells, revealed a low-ploidy and high-ploidy characteristic. The modal values of the high-ploidy tumors covered a wide range, but near-triploid numbers appeared to be favored. The mean ratio of equivalent to actual modal chromosome number for 12 low-ploidy tumor regions was 1.03 compared to 1.05 in the high-ploidy group and 1.10 in the high-ploidy recurrent tumor group. Multiple specimens obtained from 18 malignant tumors showed similar DNA values. No clear difference between the 2 groups with respect to histopathologic type was seen; however, those in the low-ploidy group showed a tendency towards a higher degree of differentiation. Those in which the tumor was confined to one or both ovaries fell mainly in the low-ploidy group; this group showing a significantly better survival rate than those in which there was spread beyond the ovaries.

- 2537 ABNORMAL HORMONE RESPONSES OF AN ADRENAL CORTICAL CANCER ADENYL CYCLASE. (E.) Schorr, I. (Dept. Med., U. North Carolina, Chapel Hill) and R. L. Ney. *J Clin Invest* 50(6):1295-1300, 1971.

Adenyl cyclase was assayed in the subcellular fractions of a corticosterone-producing adrenocortical carcinoma of the rat. Enzyme activity was found in all particulate fractions of normal rat adrenals and tumor tissue. The fractions examined were 1000 g particles, 10,000 g particles and 105,000 g particles. Activity was lowest in the 105,000 g fraction. Adenyl cyclase activity in each of the fractions of tumor normal adrenal was stimulated by ACTH, although responses of the 105,000 g fractions were small. The response of the enzyme to a given concentration of ACTH was usually more pronounced in tumor tissue than in normal adrenals. The lowest effective stimulating concentration of ACTH for malignant and normal tissue was 0.051 U/ml. Sodium fluoride also stimulated adenyl cyclase activity in normal adrenal tissue 8-fold, but had only a small effect on malignant adrenal tissue.

nephrine and norepinephrine stimulated adenylyl cyclase activity in the tumor tissue but not in normal renal tissue. Tumor cyclase was not responsive to angiotensin, vasopressin, glucagon, insulin, growth hormone, parathyroid hormone or thyrocalcitonin.

3 CHROMOSOMAL CHARACTERISTICS OF THE NK/Ly MOUSE ASCITES TUMOUR PASSAGED ON AB/Jena-Ko. STRAIN MICE. (E.) Seidlova, A. (Fac. Natural Sciences, P. J. Safarik U., Kosice, Czechoslovakia) and J. Horak. *Neoplasma* 18(1):19-26, 1971.

Specimens of NK/Ly ascites tumor were removed from AB mice and prepared for chromosome study; tumor had been transplanted to the donor mice and in its 26th passage. Tumor cells in metaphase showed marked aneuploidy, and most of the cells in metaphase were diploid. The modal number of chromosomes was 42. A large telocentric A chromosome with marked achromatic space and a large metacentric chromosome were seen in tumor cell karyotype preparations. Tumor cell metaphases also showed 1-3 minute chromosomes. It was found that 0.93% of tumor cells had spontaneous aberrations (translocations).

THE ENERGY METABOLISM OF NOVIKOFF ASCITES HEPATOMA CELLS: I. THE EFFECTS OF GLUCOSE ON THE INTRACELLULAR LEVEL OF ADENINE NUCLEOTIDES. (E.) J. W. (Mc Gill U. Cancer Res. Unit., Montreal, Quebec, Canada) and P. G. Scholefield. *Canad J Biochem* 49(6):686-694, 1971.

On addition of glucose 5 mM (or mannose) to freshly washed Novikoff ascites hepatoma cells resulted in an increase in the level of high energy nucleoside phosphates. Analysis of changes in the levels of specific adenine nucleotides showed that the decrease in ATP-hydrolyzable nucleotide phosphates was paralleled by a rapid loss of ATP which reached a minimum 1-3 min after the addition of glucose; a 50% decrease in the total adenine nucleotide pool was also observed. Subsequently, there was a constant rate of regeneration for 20-30 min which reached a new steady state in 1 hr; the low constant levels of AMP and ADP during this time suggested that the regeneration of AMP was the limiting step. Thin layer chromatography analysis of acid-soluble fractions of reaction mixtures indicated that 50% of the adenine nucleotide pool was catabolyzed within the first 10 min after the addition of glucose to give mainly hypoxanthine. Hadacidin (0.5 mM or more) inhibited the conversion of hypoxanthine to adenine nucleotides by 25% between 10 min after the addition of glucose; the addition of adenine to the reaction mixture reversed the inhibitory effect of hadacidin, indicating that AMP regeneration was also occurring by the reaction of hypoxanthine with phosphoribosyl pyrophosphate. The phenomenon of ATP depletion which occurs with the addition of glucose to freshly washed Novikoff cells is probably due to utilization of ATP for restoration of electrolyte balance; preincubation of cells in medium to allow restoration of electrolyte balance eliminated the ATP depletion.

2540 DIFFERENCES IN THE *IN VITRO* AMINO ACID LABELLING PATTERN OF MITOCHONDRIA FROM MELANOMA AND LIVER. (E.) Birkmayer, G. D. (Derm. Clin. U. Munich, Germany), and B.-R. Balda. *Febs Letters* 15(2):156-160, 1971.

Mitochondria isolated from 5 livers and 5 tumors of female Syrian hamsters receiving serial s.c. transplantation of an amelanotic hamster melanoma were incubated with various labeled amino acids and subsequently treated with cycloheximide, chloramphenicol and proflavine. The isolated mitochondria of the melanoma incorporated the amino acids at a rate more than 4 times greater than that of the liver mitochondria. Cycloheximide had no effect on label incorporation into the melanoma mitochondria but inhibited this in liver mitochondria. Chloramphenicol produced a 50% inhibition of label incorporation in melanoma mitochondria and a 38% inhibition in liver mitochondria, while proflavine produced no inhibition in the melanoma mitochondria and a 30% inhibition in liver mitochondria. Sonication of melanoma mitochondria in phosphate buffer solubilized about 1/4 of the total radioactivity incorporated and about 60% of the protein, while in liver mitochondria, 45% of the protein and 6% of the total radioactivity was solubilized. The labelling pattern produced at least 3 bands on gel electrophoresis at 2.5 cm, 3.3 cm and 4.0 cm which were radioactive in the melanoma but were unlabeled in the liver mitochondria.

2541 THE TYROSINASES OF MOUSE MELANOMA: ISOLATION AND MOLECULAR PROPERTIES. (E.) Burnett, J. B. (Massachusetts General Hosp., Boston). *J Biol Chem* 246(10):3079-3091, 1971.

The tyrosinase activity in Harding-Passey melanoma maintained by serial s.c. transplantation in Swiss white mice was determined by spectrophotometric or manometric techniques. Two soluble and 1 insoluble fractions of active tyrosinase were obtained; the 2 soluble fractions had molecular weights of 66,000 and 56,700, resp. The amounts of amino acid residues in the 2 fractions of histidine, arginine, serine, glycine, alanine, isoleucine, methionine, phenylalanine, glutamic acid and tryptophan approximated each other in weight, whereas aspartic acid and threonine showed the greatest variation; lysine, proline, half-cystine, valine, leucine, and tyrosine also showed marked variation. These results suggest that the molecule of tyrosinase may be a single chain rather than a multichain protein.

2542 LYSOSOMES IN MOUSE MELANOMA. (E.) Seiji, M. (Dept. Derm., Tohoku U. Sch. Med., Sendai, Japan) and N. Otaki. *J Invest Derm* 56(6):436-440, 1971.

Lysosomal enzyme activities were measured in centrifugation fractions of the B16 mouse melanoma, and correlations between enzyme activity and tumor growth were observed in transplantation experiments with the same tumor. Tyrosinase and succinate dehydrogenase

were confined mainly to the fraction of tumor tissue preparation containing mitochondria, lysosomes and some microsomes. Cathepsin and acid phosphatase were located in this fraction, but were also found in the cell supernatant. In related experiments, the melanoma was transplanted to D-D line mice, 5 of which were killed every 4th day for 29 days. Tumors were resected, weighed and centrifuged at $11,000 \times g$ for 20 min. Nine days after transplantation of the tumor, its weight and size began to increase progressively; the tumors eventually became necrotic, and most mice had died by 29 days after transplantation. Acid phosphatase activity increased from the time of tumor transplantation, and reached its maximum by 5-9 days after transplantation, β -glucuronidase showed a similar course. Cathepsin activity declined from transplantation until day 5, and thereafter increased sharply, and reached its maximum on day 9. An increase in succinate dehydrogenase paralleled the increase in tumor weight until day 21 after transplantation. Tyrosinase activity reached its maximum on day 9. By day 21-29 after transplantation, most enzymes had declined to levels similar to those found at the time of transplantation of the melanoma.

- 2543 ULTRASTRUCTURAL STUDIES OF HARDING-PASSEY MOUSE MELANOMA. (E.) Seiji, M. (Dept. Derm., Tokyo Med. and Dental U., Sch. Med., Japan) and N. Otaki. *J Invest Derm* 56(6) 430-435, 1971.

Hardin-Passey mouse melanomas were serially transplanted to a Swiss strain of mice and were examined by electron microscopy. Three types of cells were revealed: a melanin-producing cell, a melanin-containing cell and a melanin-producing and -containing cell. In the melanin-containing cells, melanosomes in various developmental stages were scattered throughout the cytoplasm. The shape of the melanosomes was roughly spherical and the diameters varied from 0.3 to 0.6 μ . In the melanin-containing cell, melanosomes were present in the form of melanosome complexes. These complexes are believed to be some sort of a lysosome formed by autophagy. The melanin-producing and -containing cell is assumed to be the aged melanocyte and the melanin-containing cell to be the older melanocyte.

- 2544 NUCLEOTIDE POOLS OF NOVIKOFF RAT HEPATOMA CELLS GROWING IN SUSPENSION CULTURE: II. INDEPENDENT NUCLEOTIDE POOLS FOR NUCLEIC ACID SYNTHESIS. (E.) Plagemann, P. G. W. (Med. Sch. U. Minnesota, Minneapolis). *J Cell Physiol* 77(2): 241-258, 1971.

Novikoff rat hepatoma cells were incubated with 3 concentrations of 3H -5-uridine (100, 10 and 0.5 μM) for 20 min followed by washing with warm medium and incubation in fresh medium either free of uridine or containing unlabeled uridine and were analyzed for radioactivity in total cell material and in acid-soluble material. After 20 min of labeling 80-85% of the total label associated with the cells was found in acid-soluble material regardless of the

uridine concentration during the pulse period; however, the washing procedure immediately stopped further incorporation and was followed by a slow constant rate of radioactive loss during the chase. Further incubation in fresh medium containing unlabeled uridine resulted in complete cessation of incorporation of label into acid-insoluble material. At the end of the 80-min chase period at least 50% of the label in the acid-soluble pool was present as UTP, regardless of uridine concentration or whether or not unlabeled uridine was present during the chase period. In cells resuspended in labeled uridine, the amount of label in both total cell material and acid-insoluble material began to increase immediately after re-addition of label to pulse-chased cells and the rates of incorporation were approximately the same as during the pulse-labeling period. Thus, the added uridine appeared to enter RNA without passing through the pool of UTP accumulated during the initial labeling period. Substitution of adenosine for uridine resulted in similar findings but thymidine seemed to be incorporated through a single pool.

- 2545 MICROBODIES OF MORRIS HEPATOMAS. (E.) Mochizuki, Y. (Dept. Path., U. Chicago, Ill.), Z. Hruban, H. P. Morris, A. Slesers and J. Vigil. *Cancer Res* 31 (6):763-773, 1971.

Thirty-six varieties of Morris hepatomas were examined for the presence of microbodies and for activity of 3 microbody enzymes: catalase, urate oxidase and D-amino acid oxidase. The hepatomas from rats were either fast-growing, slow-growing or of intermediate growth rate. Microbodies were present in all hepatomas examined except for hepatomas 3683 (fast-growing), 7794A (intermediate) and BRL-4-C-3 (slow-growing). Microbodies were seen as round or ovoid particles limited by a membrane; they were always in contact with smooth portions of rough cisternae and sometimes with tubular endoplasmic reticulum and lipid droplets. Microbodies were relatively rare in fast-growing hepatomas, and those which were seen in fast-growing tumors were comparatively small (0.2-0.4 μ). Crystalloids were also rare in fast-growing hepatomas. In intermediate growth rate hepatomas, microbodies were more abundant and larger (0.4-1.0 μ), and crystalloids were common. Slow-growing hepatomas contained microbodies with frequency comparable to or exceeding the frequency with which microbodies were found in intermediate-rate tumors. These microbodies were larger than those found in intermediate-rate tumors (0.2-1.3 μ); crystalloids were seen in slow-growing tumors with about the frequency with which they were seen in intermediate-rate tumors. Hepatomas with numerous large microbodies (e.g., slow-growing and intermediate growth rate tumors) usually had high catalase and D-amino acid oxidase activity levels (e.g., 50-100 U catalase/mg protein and 40-80 U D-amino acid oxidase/mg protein). Hepatomas with scarce or small microbodies (e.g., fast-growing tumors) usually had relatively low values for catalase and D-amino acid oxidase activity (e.g., 3-12 U catalase/mg protein and 0-7 U D-amino acid oxidase/mg protein).

protein). Hepatomas with high urate oxidase activity usually had large crystalloids in the bodies. Urate oxidase and D-amino acid oxidase activities did not correlate with hepatoma growth rate.

DIFFERENCE OF RNA POPULATION BETWEEN NORMAL LIVER AND HEPATOMA AH-130. (E.) Ono, T. (Cancer Inst., Tokyo, Japan), M. Kawamura, M. Hyodo and K. Wakabayashi. *Gann* 62(1):31-40, 1971.

In a rapidly growing rat ascites hepatoma designated AH-130 was compared with RNA in normal rat liver using RNA-DNA hybridization techniques in order to determine the hybridization efficiency of hepatoma RNA compared with that of normal liver. Competition experiments revealed that the hepatoma lacked a fraction of liver cell RNA present in normal liver and that tumor cell liver RNA synthesized a fraction not found in normal liver. These results were obtained using whole cell RNA in the competition experiments; when nuclear RNA was used it was found that a fraction of liver cell RNA present in normal cells was missing from hepatoma RNA, but no RNA fractions present in hepatoma RNA were absent from normal cell RNA.

ENZYME PATTERNS IN A GROUP TRANSPLANTABLE MOUSE HEPATOMAS OF DIFFERENT GROWTH RATES. (E.) Bresnick, E. (Dept. Pharmac., Baylor Coll. of Medicine, Houston, Texas), E. D. Mayfield, Jr., A. G. S. and R. A. Liebelt. *Cancer Res* 31(7):743-751, 1971.

Hybrid mice were given s.c. implantations of 1-2 fragments of viable spontaneous, methylcholanthrene-induced hepatoma tissue and the resulting tumor tissue was assayed for enzyme activity. The time from inoculation until the tumor reached approximately 1 cm in diameter ranged from 30-60 days for the first transplant generation. Subsequent transplantation generations revealed a progressive decrease in growth period. The morphological pattern in general remained stable compared to the primary tumor structure in all except 2 hepatomas. Distribution of glycogen was similar to that of normal liver in approximately half of the hepatoma lines in the first transplant generation; however, 5 hepatomas were free of histochemically demonstrable glycogen following subsequent transplantation. Cytoplasmic inclusion bodies, present in primary tumors, were absent in transplants. Glutamate transcarbamylase was elevated in all but one hepatoma while ornithine transcarbamylase decreased in all hepatomas; carbamylphosphate synthetase revealed 10% of the activity found in normal liver in only 1 hepatoma. Uracil reductase activity was less than 10% of normal in all hepatomas, except in 2 hepatomas which revealed 25% and 50% activity. The individuality of enzymic complement could be an expression of genetic origin or of manner of induction of the neoplasm.

2548 CHOLESTEROL BIOSYNTHESIS IN TRANSPLANTABLE HEPATOMAS: EVIDENCE FOR IMPAIRMENT OF UPTAKE AND STORAGE OF DIETARY CHOLESTEROL. (E.) Harry, D. S. (Royal Free Hosp., London, England), H. P. Morris and N. McIntyre. *J Lipid Res* 12(3):313-317, 1971.

Rats bearing transplanted Morris hepatomas (numbers 7793, 7794A and 7787) were fed a diet containing 2% cholesterol for periods of up to 21 days, and cholesterol biosynthesis was observed in tumor-bearing and tumor-free rats on the cholesterol-rich diet. Incorporation of acetate into cholesterol was inhibited by cholesterol feeding, but acetate incorporation was unaffected in tumor tissue. Livers of cholesterol-fed rats accumulated large amounts of cholesterol esters; however, the hepatomas showed little or no increase in cholesterol ester content. When tritium-labeled cholesterol-1 α was administered intragastrically to tumor-bearing rats it was found that the uptake of ^3H by tumors was slower than uptake of ^3H by normal livers. Apparently, the insensitivity of cholesterol biosynthesis to dietary cholesterol in Morris hepatomas was due to impaired incorporation and storage of dietary cholesterol.

2549 SURVEY OF SOME ENZYME PATTERNS IN TRANSPLANTABLE REUBER MOUSE HEPATOMAS. (E.) Reynolds, R. D. (McArdle Lab., U. Wisconsin Med. Ctr., Madison), V. R. Potter, H. C. Pitot and M. D. Reuber. *Cancer Res* 31(6):808-812, 1971.

Spontaneously arising hepatomas in C3H x Y hybrid mice were transplanted s.c. bilaterally into the hind legs of 4-7-wk-old C3H x Y mice and were then used for enzyme pattern surveys. Tyrosine aminotransferase, serine dehydratase and citrate cleavage enzyme generally showed lower values in host liver; however, tyrosine aminotransferase levels rose in response to a high-protein diet in 4 hosts with hepatomas. Glucose-6-phosphate dehydrogenase showed similar values in all host livers and hepatomas studied. The results obtained resemble those obtained from a series of diploid Morris hepatomas.

2550 DISTINCTIVE PROPERTIES OF FERRITIN FROM THE REUBER H-35 RAT HEPATOMA. (E.) Lee, J. C. K. (U. Rochester Med. Ctr., N. Y.) and G. W. Richter. *Cancer Res* 31(5):566-572, 1971.

S.C. hepatoma transplants grown in female weanling ACI rats loaded with iron were pooled, analyzed and compared with normal rat liver by means of electrophoresis and spectrophotometric analysis. The proportions of ferritin obtained from H-35 hepatomas were 90.2% α (monomer), 8.9% β (dimer), and 0.9% γ (trimer), compared to ferritin from ACI rat liver which contained 80.9% α (monomer), 13.7% β (dimer), and 5.3% γ (trimer). The isoelectric point of H-35 ferritin, pH 4.95 ± 0.03 , was significantly lower than that of ACI rat liver ferritin, pH 5.20 ± 0.02 . The ratios of ferritin monomers from H-35 tumors to ferritin from ACI rat livers in the pH 5.5 eluate

from an ion exchange column was higher than at pH 7.2. Quantitative amino acid analysis revealed significant differences in all but aspartic acid, glycine and phenylalanine content. Ultracentrifugation gave a sedimentation coefficient for ACI rat liver apoferritin of 17.80S and for H-35 hepatoma of 17.94S. Both kinds of ferritin produced a plateau of maximal absorption between 230 and 280 nm, and above 280 nm the absorbance slowly declined. Crystal formation revealed similar octahedral structures in both ferritins; these structures were indistinguishable from each other when examined by electron microscopy.

- 2551 TURNOVER OF TYROSINE TRANSAMINASE IN CULTURED HEPATOMA CELLS AFTER INHIBITION OF PROTEIN SYNTHESIS. (E.) Barker, K. L. (Oak Ridge Natl. Lab., Tennessee) K. L. Lee and F. T. Kenney. *Biochem Biophys Res Commun* 43(5):1132-1138, 1971.

Hydrocortisone-induced monolayer cell cultures of the Reuber (H-35) hepatoma were treated with cycloheximide or puromycin to study the dynamics of tyrosine transaminase turnover. Addition of 5 µg/ml of cycloheximide to H-35 cells maximally induced with 5×10^{-7} mole of hydrocortisone led to a decline in enzyme levels during the first hr, when the half-life of the enzyme became 1.6 hr. The rate of enzyme inactivation decreased thereafter, so that its half-life became about 10 hr between 4 and 9 hr after addition of the inhibitor. The cells were functionally viable after 3 hr treatment with cycloheximide. The levels of tyrosine transaminase increased to 96% of those present in maximally induced uninhibited cells 1 hr after removal of the inhibitor. The cells retained their capacity both to inactivate tyrosine transaminase and to have the synthesis of this enzyme reinduced by hydrocortisone. Tyrosine transaminase turnover was blocked between 4 and 6 hr after addition of puromycin. The reversibility of the cycloheximide effect on tyrosine transaminase suggests that no generalized toxic effects occurred in the cultured cells.

- 2552 INFLUENCE OF SPLENECTOMY ON THE DEVELOPMENT OF LEUKEMIA IN MALE MICE OF THE ICRC STRAIN. (E.) Pai, S. R. (Cancer Res. Inst., Tata Memorial Centre, Parel, Bombay 12, India) and K. J. Ranadive. *Life Sci* 10(8):475-479, 1971.

Twenty randomly selected weanling male mice of the ICRC strain were subjected to splenectomy in order to investigate the role of the spleen in the development of spontaneous leukemia. Another group of intact males were given a previous i.p. injection of leukemic spleen homogenate and were subjected to splenectomy when palpable tumors developed. One of 20 intact control mice developed a generalized lymphocytic leukemia at 14.5 months, and 3 out of 20 splenectomized males developed lymphosarcoma at 9, 11 and 13 months. None of the splenectomized animals developed leukemia following transplant of leukemic spleen cells, while 6 out of 6 intact litter-mate controls given leukemic spleen cells

developed leukemia. Splenectomy after the development of palpable tumors had no prophylactic effect on the hosts since all the animals receiving transplants died 1 wk after the operation. Removal of the spleen did not reduce the incidence of leukemia under the given experimental conditions, which indicates that organs other than the spleen are involved in the development of leukemia.

- 2553 GLUCOSE AND ACETATE UTILIZATION BY HYPERPLASTIC, ALVEOLAR NODULE OUTGROWTHS FROM ADENOCARCINOMAS OF MOUSE MAMMARY GLAND. (E.) Bartley, J. C. (Children's Hosp. Med. Ctr. No. 1, California, Oakland), H. McGrath and S. Abraham. *Cancer Res* 31(5):527-537, 1971.

Mammary tissue from normal lactating C3H mice, pregnant and lactating mice with mammary adenocarcinoma, and from mice with hyperplastic alveolar nodules was studied for the utilization of radioactive glucose-1-¹⁴C, glucose-6-¹⁴C, -6³H, and 1-¹⁴C. Lactate production, CO₂ production, 1-¹⁴C and pentose phosphate cycle activity were also measured. Normal lactating mammary glands showed the highest metabolic activity in all parameters except lactate production; tumor tissue exhibited the lowest metabolic activity. The values of the various parameters for hyperplastic alveolar nodule tissues were intermediate to values recorded for normal tissue from suckled mice. The addition of glucose to tissue preparations stimulated the incorporation of glucose into fatty acids; glucose stimulation was not marked in tumor tissue as in normal mammary tissue. Glucose and acetate utilization by normal mammary tissue from pregnant mice was similar to that of hyperplastic alveolar nodule tissue, and the utilization of glucose and acetate in tumor tissue was minimal.

- 2554 THE ANALYSIS OF MALIGNANCY BY CELL HYBRIDS BETWEEN TUMOUR CELLS AND NORMAL CELLS. I. HYBRIDS BETWEEN TUMOUR CELLS AND NORMAL CELLS. DERIVATIVES. (E.) Klein, G. (Dept. Tumour Biology, Karolinska Inst., Stockholm, Sweden), U. Bregander, F. Wiener and H. Harris. *J Cell Sci* 8(3) 659-671, 1971.

Hybrids were produced by fusing normal L cells with the A9, B82 or A9RI cell line with tumor cell lines, and the growth of these cell hybrids was examined by inoculating them in syngeneic hosts. Tumor cells used in the fusion production of hybrids included an Ehrlich tumor derived from a mouse, 2 ascites sarcomas (SEWA and SEWA-2) and 2 lymphomas (YAC and YACIR). Ehrlich/A9 hybrids contained the marker chromosomes peculiar to each of the parent lines, and had a modal number of 128 chromosomes. They had a low level of tumorigenicity in irradiated newborn mice, indicating the high malignancy of the Ehrlich tumor cells was not transmitted to its hybrid. Cells from the hybrids which did ensue after inoculation of syngeneic hosts with the Ehrlich/A9 tumor cells had a lower chromosome number than did the hybrid cells which contained marker chromosomes of both hybrid

rid cells produced by fusing A9 cells with cells from the other tumors had modal chromosome numbers approximately equaling the sum of the modal numbers of each parent cell. In all cases, the malignancy of the tumor cells was modified by fusion with the other cells; the hybrids had a low malignancy compared with that of the parent tumor cell. Chromosome numbers in hybrid tumor cells were lower in all cases than in the hybrids. B82 cells also appeared to suppress the malignancy of Ehrlich tumor cells in hybrids of the 2 cells. When Ehrlich cells were fused with A9RI cells, the malignancy of the hybrid was again found to be slight compared to that of the Ehrlich cell parent. When Ehrlich/A9 hybrid cells were grown *in vitro* for 18 months (a period judged sufficiently long for some general chromosome loss to occur) prior to inoculation into mice, the malignancy of the hybrid cells was not markedly enhanced, suggesting that the loss of a *specific* chromosome (other than a general reduction in number) is required for hybrid cells to grow *in vivo*.

5 A SPONTANEOUS MESENCHYMAL CELL NEOPLASM IN THE ADULT NEWT, *DIEMICTYLUS VIRIDESCENS*.

Burns, E. R. (Dept. Anat., U. Arkansas Med. C., Little Rock) and H. J. White. *Cancer Res* 31(5):826-829, 1971.

Tumor mass was seen protruding from the left side of an American newt (*Diemictylus viridescens*); the tumor had been collected in an unpolluted fresh water pond and had not been deliberately inbred. Multiple parastitic inflammatory lesions are not uncommon in the order Urodela, cancerous lesions are rare. On light microscopy, the tumor was found to be composed of epidermal and muscle cells, and had invaded skeletal muscle tissue. Tumor cells showed varying degrees of nuclear and cytoplasmic pleomorphism; cells contained large hyperchromatic and pycnotic nuclei and occasionally had prominent nucleoli. No extensive necrosis was seen in the tumor and no mitotic figures were present; PAS-positive granules were seen in the cytoplasm of tumor cells. The lesion was described as mesenchymal cell neoplasm.

6 PLASMA RENIN ACTIVITY IN WILM'S TUMOUR.

(E.) Voute, P. A., Jr. (Emma Child. Hosp., Amsterdam, Netherlands), J. van der Meer and W. Gaard-Kloosterziel. *Acta Endocr* 67(1):197-202, 1971.

Plasma renin activity (PRA) was assayed in 8 children with Wilm's tumor, both before and after nephrectomy in 5 of the cases. The patients ranged in age from 1 yr and 8 months to almost 4 yr, and 6 males and 2 were females. Five of the patients had tumor metastases. The level of PRA was lower in all children than in children with Wilm's tumor before nephrectomy; PRA for normals range from 35-100 ng/10 ml/3 hr, compared to PRA for Wilm's tumor patients prior to nephrectomy which range from 150-1000 ng/10 ml/3 hr. Post-nephrectomy values for PRA in the Wilm's tumor group were similar to those seen in normal children.

2557 SOME BIOCHEMICAL AND CYTOGENETIC PROPERTIES OF RAT THYROID TUMORS. (E.) Wu, C. (Dept. Biol. Chem., U. Michigan, Ann Arbor), A. A. Al-Saadi, R. C. Ling and K. L. McKinnie. *Cancer Res* 31(5):577-582, 1971.

Tumors produced by s.c. transplantation of the goiters of rats fed a Remington low-iodine diet for 12-16 months into the flanks of thyroidectomized Fischer rats and then into intact rats were subjected to biochemical and cytogenetic studies. Three of the 4 transitional tumors studied were well-differentiated adenomas and 1 was moderately to poorly differentiated. All 4 tumors had a modal chromosome number of 42 in 63-84% of the cells; the percentage of aneuploidy ranged from 16-36% with 10% or more of the cells having 41 chromosomes. The 4 autonomous tumors studied were all undifferentiated, fast-growing, metastasizing carcinomas. All autonomous tumors had numerically and/or structurally altered karyotypes in 100% of their cells. Most of the cells of autonomous tumors were characterized by the loss of 1 chromosome of Pair 15; the dropping of this chromosome may be associated with the progression of the tumor from the transitional to the autonomous stage. The uptake of ^{131}I by the thyroid of tumor-bearing animals was lower than the uptake by normal thyroid; no difference in uptake was observed between rats bearing autonomous or transitional tumors. The uptake of ^{131}I by the tumors was about 1/15th that of the total uptake of the host thyroid; the labeled iodine entering the tumor appeared not to be incorporated into organic compounds. The activity of iodide peroxidase was decreased in the thyroid of animals bearing thyroid tumors (transitional or autonomous). The transitional tumors showed a level of enzyme activity intermediate between that of normal and host thyroid. No measurable peroxidase activity was found in any of the autonomous tumors.

2558 ELECTRON MICROSCOPIC OBSERVATIONS ON STRUCTURES RESEMBLING MYXOVIRUS IN HUMAN SARCOMAS. (E.) Györkey, F. (VA Hosp., Houston, Texas), J. G. Sinkovics and P. Györkey. *Cancer* 27(6):1449-1454, 1971.

Cytoplasmic structures resembling strands of paramyxovirus ribonucleoprotein were observed under the electron microscope in preparations of human tumors of mesenchymal origin; tumor material included biopsies of rhabdomyosarcomas, liposarcomas, chondrosarcomas, osteosarcomas, fibrosarcomas, neurofibrosarcomas and Kaposi's sarcoma, and primary tissue cultures of rhabdomyosarcomas, chondrosarcomas, fibrosarcomas and osteosarcomas. All rhabdomyosarcomas and some liposarcomas, osteosarcomas, fibrosarcomas and Kaposi's sarcomas contained filamentous and tubular cytoplasmic structures. Structures were found in tissue cultures as well as in biopsy material. The filamentous and tubular structures were located in the cytoplasm in aggregates of varying sizes; in some cases the aggregates were membrane-bound. In Kaposi's sarcoma, the structures were found between nuclear membranes. The filaments measured 200-220 Å in diameter and up to 1000 Å in length. Fila-

ments in cross section were sometimes electron-dense and sometimes lucent. The nature and function of these structures is unknown.

- 2559 MELANOTIC AND AMELANOTIC MELANOMAS IN XIPHOPHORIN FISH. (E.) Vielkind, J. (Genet. Inst., Justus Liebig-U. Giessen, German), U. Vielkind and P. Anders. *Cancer Res* 31(6): 868-875, 1971.

Preparations of inherited melanotic and albino melanomas carried by hybrids of the platyfish and swordtail species of xiphophorus fish were examined under the electron microscope; among both pigmented and albino melanomas, a rapidly growing form and a more slowly growing form were examined. Rapidly growing melanotic melanomas were found to consist of melanocytes only, which were slightly dendritic or spindle-shaped and contained ovoid nuclei. Rapidly growing albino melanoma cells were relatively anaplastic, but otherwise resembled rapidly growing melanotic melanoma cells; however, in the albino cells there were only a few premelanosomes in the cytoplasm, while in melanotic melanomas the cytoplasm contained abundant premelanosomes. Slowly growing melanotic melanomas of some albino hybrids consisted of large dendritic melanocytes. Albino melanomas were found to possess a higher DNA content/U fresh weight than melanotic melanomas. The albino melanomas appeared to be more malignant than the melanotic melanomas.

- 2560 RECENT ADVANCES IN THE ULTRASTRUCTURE OF MALIGNANT MELANOMA. (E.) Cesarini, J. P. (Regional Anti-Cancer Ctr., Marseille, France). *Rev Europ Etud Clin Biol* 16(4):316-322, 1971.

Melanocytes from benign and malignant melanomas were examined under the electron microscope. No alteration of the maturation of the melanosomes within the melanocytes or of the deposition of pigment was seen in benign tumors, and the protein in the melanocytes remained regular. The protein structure of melanocytes in pigmented malignant melanomas was disorganized, folded and broken; the deposition of melanin on the protein was irregular. The maturation of the melanosomes was disrupted in malignant cells. In the Dubreuilh-Hutchinson melanosis which affects elderly women, an increase in melanocytes at the expense of keratinocytes was seen to mark the onset of a precancerous condition. Ultrastructural examination of amelanotic melanoma melanocytes showed 2 cell types: one type of cell contained premelanosomes which did not develop into mature melanosomes, and the other contained no premelanosomes.

- 2561 DNA POLYMERASES FROM HUMAN CELLS. (E.) Weissbach, A. (Roche Inst. Molec. Biol., Nutley, N. J.), A. Schlabach, B. Fridlender and A. Bolden. *Nature* 231(23):167-170, 1971.

Two DNA polymerase activities have been isolated from the nucleus of HeLa cells and in the normal

human lung diploid line WI-38. One of the DNA polymerase activities (I) was found only in the nucleus in normal conditions, and the other (II) resembled the single DNA polymerase activity found in the cytoplasm. The HeLa cell cytoplasmic and nuclear enzyme II showed an optimal response with 5-10 mM Mg^{2+} , whereas nuclear enzyme I approached maximum activity at 15-26 mM Mg^{2+} . All 3 DNA polymerases were inhibited by high salt concentrations. *p*-Chloromercuribenzoate (25 μ M) did not affect nuclear enzyme I, but inhibited nuclear enzyme II and the cytoplasmic enzyme almost completely. Nuclear enzyme I was 2-3 times more sensitive to inactivation in the presence of 200 μ g/ml of bovine serum albumin at 45°C than the other DNA polymerases. DNase I-treated double stranded DNA was an effective primer for the HeLa DNA polymerase. The dependence of the reaction on all 4 deoxyribonucleoside triphosphates was established. Mycoplasma and other contaminating organisms were not detected in the HeLa cell cultures from which the DNA polymerases were isolated.

- 2562 "BENIGN METASTASIZING GOITER" OF CONGENITAL ORIGIN: AN EXPERIMENTAL STUDY WITH THE TRANSPLANTABLE THYROID TUMOR OF THE RAT. (E.) Matvinov, J. (U. Michigan Sch. Med., Ann Arbor), R. H. Nishiyama, A. Lalli and G. Poissant. *Cancer Res* 31(2):288-296, 1971.

Male rats were given injections of 100,000 cells from a papillary-follicular thyroid tumor containing apparently normal follicles; rats were injected into the heart, jugular or mesenteric vein, medullary canal of the femur, or subcutaneously. All animals developed tumor implants following injection of tumor cells; rats injected in the heart developed 40 lung tumor implants and 4-5 liver tumor implants. Tumors developed more rarely in spleen, kidney, and vertebrae. Some tumor implants consisted of normal-appearing follicles in lungs, kidneys, spleen, or vertebrae and were virtually indistinguishable from implants of normal thyroid tissue in the same organs. Injection of tumor cells in the heart produced tumor implants in all lobes of the liver which appeared as papillary tissues and normal-appearing follicles. Papillary and papillary-follicular implants were seen in muscle which did not contain normal-appearing follicles. Implants similar to the parent tumor were seen in the medullary canal of the femur and in the skin. Iodine metabolism was studied in the implants by observing the concentrations of ^{131}I injected into rats with tumor cell implants. The ^{131}I uptake of the thyroid gland in tumor-bearing rats was lower than in rats without tumors; the protein-bound iodine in tumor-bearing rats (5.0-100 μ g/ml) was higher than that in tumor-free rats (1.0-100 μ g/ml). The ^{131}I uptake by s.c. implants was higher than the uptake by the thyroid gland; however, the tissue of the implants was 26 times as active on a per unit wt basis than the thyroid tissue samples dissected from tumor implants from the same rats. Tumor implants in the thyroid and other internal organs concentrated about 4 times more ^{131}I than similar samples from s.c. tumor implants. The concentration of ^{131}I was highest in the normal-appearing lung follicles. The differentiation

Baylor Coll. Med., Houston, Texas), H. J. Spjut,
M. N. Smith and F. Rapp. *Cancer* 27(6):1440-1448,
1971.

3):361-366, 1971.

Electron microscopic examination of cells prepared from an osteoblastic osteosarcoma developed in the right humerus of a 15-yr-old male revealed branched tubular intracytoplasmic structures in primary tumor cells and in lung metastases. Tubular structures were seen in tumor cells, endothelial cells and lymphocytes and were localized in the endoplasmic reticulum. These tubular structures had 2 distinct patterns: in one pattern, the cisternae of the endoplasmic reticulum were dilated and the tubules had a uniform diameter; and in the other pattern, the endoplasmic reticulum surrounded the tubules tightly and the latter had a sieve-like appearance. The tubules appeared to have originated by the development of particles condensed from the endoplasmic reticulum. The tubular structures measured 20-31 μ m in diameter, and had a core containing fine granules. Although it was suggested that the tubules might be measles virus nucleocapsids, this hypothesis was rejected on the basis of morphological differences between the osteosarcoma tubules and measles virus nucleocapsids.

SE OF THE DISEASE. (Ger.) Müller, D. (Med. Col. Clin., Tübingen, Germany). *Acta Histochem* (pl. 9):201-206, 1971.

2566 MULTIPLE PRIMARY TUMORS INCLUDING BILATERAL BREAST CANCERS IN A MAN WITH KLINEFELTER'S SYNDROME. (E.) Coley, G. M. (Dept. Surg., Hartford Hosp., Hartford, Conn.), R. D. Otis and W. E. Clark II. *Cancer* 27(6):1476-1481, 1971.

A case report is described in which a 34-yr-old man with Klinefelter's syndrome developed, over a period of 20 yr, 6 separate primary tumors, including chondroma of the sacrum, lipoma on the back chest wall, spongioblastoma of the brain, carcinoma of the breast (Paget's disease), papillary carcinoma and cervical metastases of the thyroid, and a second Paget's carcinoma of the breast. The intervals between diagnosis of the several tumors range from 0.5-8 yr. Although associations have been reported between Klinefelter's syndrome and breast cancer, the present case was thought to be unique in view of the number of separate primary tumors. The experience of multiple tumors, especially of the breast, which occur with increased frequency in men with Klinefelter's syndrome suggests both genetic and hormonal factors are involved in the etiology of the tumors.

(E.) Nathanson, L. (Dept. Med., New England Med. Ctr., Boston, Mass.) and W. Fishman. *Cancer* 27(6):1388-1397, 1971.

Sera from 323 patients with malignancy confirmed by histologic examination was quantitated for the presence of Regan phosphatase isoenzyme. A positive identification of Reagan isoenzyme was made in 12% (39) of the patients; those suffering from ovarian and pancreatic carcinoma had the highest incidence

7-JUNE 1971

of the isoenzyme, followed by gastric, breast, and lung cancers and the sarcomas. The majority of patients who were Regan negative had a heat-stable alkaline phosphatase of less than 0.8 U. In a group of cancer patients with elevated phosphatase, an almost 3-fold greater incidence of Regan isoenzyme was observed than in the group of cancer patients unselected for hyperphosphatasemia. In addition, persons with hepatic and intestinal disease of a non-malignant nature were found to be positive for the presence of Regan isoenzyme. The biological significance of this isoenzyme seems to lie in its role as an additional carcinoembryonic system.

- 2568 ULTRASTRUCTURE OF GRANULAR CELL AMELOBLASTOMA. (E.) Navarrette, A. R. (Baylor Coll. Med., Houston, Tex.) and M. Smith. *Cancer* 27(4):948-955, 1971.

An electron microscopic study was performed on tumor tissue from a granular cell ameloblastoma developing on the jaw of a 47-yr-old Negro woman. Under the light microscope, the tumor was seen to be composed of numerous neoplastic epithelial islands in a scant, mature fibrous stroma. In the centers of the islands were large eosinophilic granular cells of varying shapes containing cytoplasmic granules of varying sizes. The granules were PAS-positive. On electron microscopic examination, tumor cells were seen to have numerous lysosome-like pleomorphic osmiophilic granules in the cytoplasm. Granules had different structures; some showed concentrically laminated membranes and others were composed of bundles of fine parallel membranes running in different directions. Large round degenerative cytoplasmic masses were also seen. In addition to the granules, cytoplasm contained round or oval mitochondria, well developed Golgi complexes and scant rough-surfaced endoplasmic reticulum. The cytoplasmic granules in the ameloblastoma resembled those seen in the granular cell myoblastoma.

- 2569 GASTRIC POLYPS: HISTOLOGIC TYPES AND THEIR RELATIONSHIP TO GASTRIC CARCINOMA. (E.) Tomasulo, J. (Dept. Path., Hosp. U. Pennsylvania, Philadelphia). *Cancer* 27(6):1346-1355, 1971.

Case histories of 97 patients with gastric polyps were studied with the result that 35% of the polyps were found to have occurred in stomachs of patients with gastric carcinoma. Neither singly occurring polyps, multiple discrete polyps nor gastric polyposis was correlated with carcinoma to a higher degree than the other polyp conditions. Hyperplastic polyps were more common than adenomatous polyps, the former accounting for 76% of cases. Hyperplastic polyps were randomly distributed throughout the stomach, while adenomatous polyps were usually located antrally and were similar to colonic polyps. Only in association with adenomatous polyps was *in situ* carcinoma seen. Fifty-nine percent of adenomatous polyps and 28% of hyperplastic polyps were associated with carcinoma.

- 2570 RIBONUCLEOPROTEIN PARTICLES INVOLVED IN HeLa MITOCHONDRIAL PROTEIN SYNTHESIS. (E.) Brega, A. (Massachusetts Inst. Tech., Cambridge) and C. Vesco. *Nature* 229(5):136-139, 1971.

The relation between ribonucleoprotein particles and protein synthesis in HeLa cell mitochondria was investigated according to functional criteria by selective labeling in the presence of suitable inhibitors. A sucrose gradient analysis of mitochondrial structures carrying nascent peptide chains after pulse-labeling of cells in the presence of pederine (which inhibits cytoplasmic protein synthesis) showed most of the incorporated radioactivity to be associated with structures of 180S or greater except for 1 small peak in the 40S position. Chloramphenicol and pederine together blocked label incorporation into both the 55S and 40S larger structures. The radioactivity of the 55S region of the sample treated with pederine disappeared during 5 min of incubation with puromycin, confirming that the label had been incorporated into nascent peptide chains. Most of the protein synthesizing structures were sensitive to antibiotics and sedimented faster than 55S, whereas most of the ethidium bromide-sensitive RNA sedimented more slowly and the 40S peak seemed to be rather unsymmetrical. Monomers and subunits were subjected to further gradient centrifugation analysis; the data obtained from these experiments suggest that 21S and 12S RNA comprise a set of ribonucleoprotein particles qualitatively similar to those already described in *Xenopus* (12S, a ribosome smaller than the cytoplasmic ribosome, composed of 2 ribosomal subunits). The 55S ribonucleoprotein particle appears to be the mitochondrial monosome, while the heavy structures the mitochondrial polyribosomes.

- 2571 FACTORS STIMULATING CELL GROWTH COMPARED BY ISOELECTRIC FOCUSING. (E.) Ecsenyi, M. (St. Bact. Lab., Stockholm, Sweden). *Exp Cell Res* 65(1):123-128, 1971.

Growth stimulating factors were extracted from human and leukemic urine, serum from patients with acute lymphomas and normal plasma. The growth stimulating capacities of these factors were studied by isoelectric focusing. A purified fraction of normal human serum showed a stimulatory effect on growth of human marrow cells. The active substances of the different materials were compared by determining the isoelectric points. All the growth factors focused at pH 4.05-4.06. The stimulating factor prepared from a medium containing embryonic mouse cells gave a lower isoelectric point than the human material, focusing at pH 3.92-3.93.

- 2572 NUCLEOTIDE POOLS OF NOVIKOFF RAT HEPATOMA CELLS GROWING IN SUSPENSION CULTURE: KINETICS OF INCORPORATION OF NUCLEOSIDES INTO NUCLEOTIDE POOLS AND POOL SIZES DURING GROWTH. (E.) Plagemann, P. G. W. (Med. Sch. U. Minnesota, Minneapolis). *J Cell Physiol* 77(2):213-240, 1971.

Novikoff rat hepatoma cells (subline N1S1-67) which had been incubated with tritium-labeled uridine, adenosine or thymidine were used to prepare RNA

hydrolysates which were chromatographically and electrophoretically examined. Subsequent to incubation with ^{14}C -4-aspartic acid, 80-90% of the radioactivity was found in RNA and the remainder was present in DNA; half of the label was found in CMP and half in GMP. The presence of uridine almost completely inhibited the incorporation of aspartic acid into nucleic acids found in alkali hydrolysates with no inhibition of label into the acid-soluble fraction was seen. Incorporation of uridine at all concentrations proceeded 6-7 times more rapidly into the acid-soluble nucleotide pool than into the acid-insoluble material, and maximum velocity was approached at 100 μM uridine in the medium. Similar results were reported for adenosine uptake, except that saturation of the transport reaction occurred at 10 μM and simple diffusion became the predominant mode of entry above 100 μM . At 200 μM , incorporation of either uridine or adenosine into total cell material followed a biphasic pattern; approximately constant rates were established for 10 min with uridine and for 120 min with adenosine followed by a rapid increase of 70-80% before a second constant level was attained.

73 THE GERMINATIVE TUMOURS OF TESTICLES. (Ger.) Schaudig, G. (Clin. Radiat. Ther., Roentgenol., U. Marburg/Lahn, Germany), L. Buchelt and F. H. Strahlentherapie 141(5):495-507, 1971.

74 CYTOGENETIC STUDIES AT VARIOUS STAGES OF DEVELOPMENT BY CHRONIC MYELOLEUKEMIA. (Rus.) Krennevskaya, M. I. (Central Inst. Hematol. Transfusion, Min. Pub. Hlth., Moscow, U.S.S.R.), T. P. Nevskaya, T. A. Cherntsova and E. I. Terentjeva. Probl. Genet 16(2):23-29, 1971.

75 ON MALIGNANT TRANSFORMATION OF ECCRINE SPIRADENOMA. (Pol.) Dabska, M. (Z. Zakladu Onkol., Nowotworow Inst. Oncol., Warsaw, Poland). Nowotwory 21(1):37-45, 1971.

76 FAMILIAL LEUKAEMIA OR A NEW SYNDROME? (Pol.) Nowakowski, T. K. (Z. I. Clin. Radiat., Wroclaw, Poland), M. Zawartka, R. Kowalski, J. Pellar and J. Wartenberg. Pediat Pol 46(4):495-502, 1971.

77 CHROMOSOME ABNORMALITIES IN A CASE OF ACUTE HISTIOLEUKAEMIA. (It.) Bersi, M. (Med. Hosp., Verbania Hosp., Novara, Italy), C. Gasparini and G. Cardini. Minerva Med 62(21):1120-1124, 1971.

78 LEUKAEMIA AND CARCINOMA. (Ger.) Werner, W. (Path. Inst., Humboldt-U. Berlin, Germany), A. Khalatbari. Arch Geschwulstforsch 37(1):9-18, 1971.

2579 SOME CHARACTERISTICS OF NEWLY SYNTHESIZED DNA FRACTIONS FROM MAMMALIAN CELLS ELUTABLE FROM METHYLATED ALBUMIN KIESELGUHR COLUMNS BY NaCl . (Ger.) Probst, H. (Physiol. Chem. Inst., U. Tübingen, Germany). Hoppe Seyler Z Physiol Chem 352(5):748-756, 1971.

2580 STUDY OF THE MORPHOLOGY AND SECRETION OF AN EXPERIMENTAL CORTICOTROPHIC TUMOR IN THE RAT. (Fr.) Pelletier, G. (Albert Einstein Coll. Med., Bronx, N.Y.), F. Peillon, M. T. Pham Hun Trung and J. Racadot. Rev Europ Etud Clin Biol 16(1):79-83, 1971.

2581 SIPPLE'S SYNDROME (PHEOCHROMOCYTOMA AND THYROID CARCINOMA) WITH BILATERAL BREAST CARCINOMA. (E.) Lima, J. B. (Dept. Surg., Kaiser Fdn. Hosp., San Francisco, Calif.) and P. D. Smith. Am J Surg 121:732-735, 1971.

2582 SMOLDERING ACUTE LEUKEMIA: CLINICAL AND CYTOGENETIC STUDIES IN SIX PATIENTS. (E.) Knospe, W. H. (Rush Presbyterian-St. Luke's Med. Ctr., Chicago, Ill.) and S. A. Gregory. Arch Intern Med 127(5):910-915, 1971.

2583 PHACOMATOSES, THE INHERITANCE OF CANCER, AND SOMATIC MUTATION. (E.) Nicholls, E. M. (Sch. Human Genet., U. New South Wales, Australia). Clin Genet 1(5-6):245-257, 1970.

2584 DNA SYNTHESIS IN CIRCULATING LYMPHOCYTES OF PATIENTS WITH MALIGNANT LYMPHOGRANULOMA. (Ger.) Huber, C. (U. Innsbruck Med. Clin., Austria), H. Huber, F. Schmalzi, B. Lederer, D. Bütterich and H. Braunsteiner. Acta Haemat 44(4):222-232, 1970.

2585 STUDIES ON TRANSFER RNA^{Phe} FROM MORRIS 5123C HEPATOMA. (E.) Gonano, F. (Inst. Gen. Path., U. Modena, Italy) and G. Pirro. Cancer Res 31(5):656-657, 1971.

2586 CHROMOSOME ANALYSIS IN THE STUDY AND DIAGNOSIS OF BENIGN AND MALIGNANT EPITHELIAL TUMORS OF THE GASTROINTESTINAL TRACT. (It.) Messinetti, S. (Inst. Path. Surg., U. Rome, Italy) and M. Moscarini. Il Progresso Medico 26(24):721-724, 1970.

2587 CATECHOLAMINE METABOLISM IN THE TISSUE OF MALIGNANT AND BENIGN TUMORS. (Ger.) Käser, H. (Swiss Center Clin. Tumor Res., Tiefenau, Bern, Switzerland), K. Türlér and P. H. Burri. Schweiz Med Wschr 101(13):484-487, 1971.

SUBJECT INDEX

ACETAMIDOFLUORENE

BILE DUCT LIGATION, N-HYDROXY-2-
ACETAMIDOFLUORENE, ADRENALECTOMY
(0908)
ETOTOLUIDIDE
AMINOBENZOIC ACID, N-2-FLUORENYLACETA-
MIDE, CARCINOGEN-INHIBITOR (0041)
ACETOXYACETAMIDOFLUORENE
2-(N-HYDROXY)ACETAMIDOFLUORENE,
PHOSPHATE ESTER, ULTIMATE
CARCINOGEN (0909)
ACETOXY-2-ACETYLAMINOFLUORENE
DNA, BINDING (1772)
DNA, POLYNUCLEOTIDES (1774)
TRNA, GUANOSINE (2199)
ACETYLAMINOFLUORENE
DERIVATIVES, RADIOACTIVE PRECURSOR
INCORPORATION, RNA AND DNA SYNTHESIS
(0408)
DIETARY INDOLE, URINARY BLADDER
TUMORS (0907)
HEPATOMA, RESISTANCE, RAT (2426)
LIVER CARCINOMA, PORPHYRINS,
RAT (2190)
METABOLITE, BINDING, RAT LIVER,
NUCLEIC ACIDS (1301)
MOUSE, BLADDER, EPITHELIUM (1300)
NITRITE, ANTICARCINOGEN, FREE RADICAL
(0042)

HALASIA

CARCINOMA, ESOPHAGUS (1700)
TINOMYCIN D
DNA SYNTHESIS, SV40 VIRUS (0662)
INVASIVE ABDOMINAL CARCINOMA (0024)
MAMMARY TUMOR SUPPRESSION,
7,12-DIMETHYLBENZ(A)ANTHRACENE
(0932)
PUROMYCIN, LYMPHOCYTES, PHYTO-
HEMAGGLUTININ (1678)

ENOCARCINOMA

BREAST CANCER, 7,12-DIMETHYLBENZAN-
THRACENE, ESTROGEN, RAT (0064)
CERVIX UTERI, CHROMOSOMES (0254)
COLON, CARCINOEMBRYONIC ANTIGEN,
LOCALIZATION (0235)
COLON, URETEROSIGMOIDOSTOMY, MAN
(0825)*
EMBRYONAL, TESTS, CHILDREN (0746)
ENDOMETRIUM, PROTEIN SULFHYDRYL
GROUPS, HUMAN (2466)
FERTILITY, ENDOMETRIAL HYPERPLASIA (0743)
IMMUNOSUPPRESSION, THYMECTOMY,
RADIATION, MICE (1552)
METASTASIS, THYROID, HUMAN (0823)
NASAL SYSTEM, WOOD DUST (0113)
PAPILLARY, GENETIC PREDISPOSITION,
FAMILIAL OVARIAN CARCINOMA (0808)
THYROID, IODINE 131 (0126)

ENOMA

BRONCHO-ALVEOLAR CANCER, SHEEP (0820)
GASTRIC, N-METHYL-N-NITROSO-N'-
ACETYLUREA, RAT (0483)
LUNG, URETHAN, RADIATION (0101)
MALIGNANT, THYROID, X-RAY (0135)
OLESCENCE
MAMMARY FIBROADENOMAS (1705)
RAPID BONE GROWTH, ACUTE MYELOID
LEUKEMIA (0375)

ADRENAL GLAND

ADRENALECTOMY, BILE DUCT LIGATION,
N-HYDROXY-2-ACETAMIDOFLUORENE
(0908)
ADRENOCORTICAL VIRILIZING CARCINOMA,
STEROIDS (1642)
CARCINOMA, CUSHING'S SYNDROME,
BILATERAL HYPERPLASIA, HORMONAL
THERAPY (0741)
CARCINOMA, FISSION NEUTRON IRRADIATION
(0532)
CARCINOMA, HUMAN, STEROID ANALYSIS
(0782)
CORTEX, LIPID HYPERPLASIA, ANILINE,
RAT (0925)
CORTICAL CARCINOMA, ESTRADIOL,
RAT (0890)
ENDOCRINE LESION, URETHANE (0498)
ESTROGEN-DEPENDENT CARCINOMA,
RNA AND DNA METABOLISM (1770)
HISTOCHEMISTRY, WHOLE BODY
IRRADIATION, RAT (1407)*
MEDULLA, PREOPTIC-ANTERIOR HYPO-
THALAMIC LESION, GANGLIONEUROMA, RAT
(1259)
NECROSIS, 7,12-DIMETHYLBENZ(A)ANTHRA-
CENE, RAT (0438)
NEUROBLASTOMA, ANTIGENS, FETUS,
(1577)
POSTCASTRATIONAL ADRENAL TUMORS,
STRAIN VARIABILITY, MICE (1199)

ADRIAMYCIN

BLASTOGENESIS IN HUMAN LYMPHOCYTES,
MUTAGENESIS IN HUMAN LYMPHOCYTES
(0699)

ADSORPTION

ADENOVIRUS TYPE 7, ERYTHROCYTE (0614)

AFLATOXIN

ACID PHOSPHATASE, LYSOSOMAL ENZYME
ACTIVITY, CHICKEN (0916)
ANALYTICAL METHODS, REVIEW (0881)*
ASPERGILLUS FLAVUS, EFFECT OF
TEMPERATURE (0519)*
B, LIVER NUCLEAR RNA, RNA POLYMERASE,
RAT (0046)
B, LYMPHOCYTE TRANSFORMATION, PHYTO-
HEMAGGLUTININ (0045)
B1, ACUTE TOXICITY, KUPFFER CELL
HYPERPLASIA, BILE DUCT EPITHELIUM,
HAMSTER (0517)*
B1, B2, G1, G2, ANIMAL FEEDS (0991)*

METABOLISM (1311)
B1, DNA LIVER, RATS (0427)
B1, ENZYME HISTOCHEMISTRY, MUCOR
HIEMALIS FUNGUS (1376)*
B1, HEPATECTOMY, RNA SYNTHESIS,
LIVER, RAT (2205)
B1, KIDNEY, RNA POLYMERASE,
MOUSE (2207)
B1, LABELED ACETATE INCORPORATION,
HUMAN SKIN LIPIDS (0918)
B1, LIVER CARCINOMA,
HEPATECTOMY, RAT (2210)
B1, LIVER MICROSOME, REPTILE, FOWL
(1309)

- B1, LIVER NUCLEIC ACID SYNTHESIS, PHENOBARBITAL (0919)
 B1, MICROSOMAL HYDROXYLASE, 3,4-BENZOPYRENE (0428)
 B1, MUTAGENESIS, DROSOPHILA (2208)
 B1, RAT LIVER, TRANSFORMATION, IN VITRO (1312)
 B1, REYE'S SYNDROME, TOXIC REACTION IN MONKEYS (1777)
 B1, RNA SYNTHESIS, LIVER CELLS (0914)
 B1, STRUCTURE-ACTIVITY RELATIONSHIP, TROUT (1308)
 B1, TWO DIMENSIONAL THIN LAYER CHROMATOGRAPHY, FOOD PRODUCTS, PEANUTS (0990)*
 BEAGLE, LIVER CHANGES (1778)
 BIOSYNTHESIS, METHIONINE ANALOGS (2267)*
 CIRRHOSIS, CARCINOGENESIS, LIVER, RAT (2206)
 DIETARY, LIVER INJURY, RHESUS MONKEY (0426)
 DNA, RNA, REVIEW (1744)
 G1, LIVER, RAT (2209)
 HEPATIC CHANGES, ENDOPLASMIC RETICULUM, MITOCHONDRIAL ATPASE, RATS (1780)
 LIPOTROPE-DEFICIENT DIET, LIVER TUMORS (0915)
 LIVER, ENZYME ACTIVITY, CITRIC ACID CYCLE (0920)
 METABOLISM IN LIVER, DEGRADATION PRODUCTS (0917)
 MYCOTOXINS, BLOOD MALIGNANCIES, LIVER CARCINOMA (1276)
 MYCOTOXINS, TUMORIGENESIS, REVIEW (0388)*
 NUCLEIC ACID SYNTHESIS, INHIBITION (0049)
 NURSING MILK, PIG, STUNTED GROWTH (0048)
 OILSEED PROTEINS, ANIMAL FEED, TOXICITY, REVIEW (0387)*
 PALMOTOXINS, EMBRYO LIVER (0425)
 PEANUTS, DIETETICS, REVIEW (0386)*
 P1, MONKEY, AFLATOXIN METABOLITE (1310)
 SWAZILAND, LIVER CARCINOMA (1781)
 TUMOR INDUCTION, NUCLEIC ACID BINDING (0047)
- AGE
 ADJUSTMENT, EPIDEMIOLOGY, MATHEMATICAL MODEL (0264)
 BENZO(A)PYRENE, ORGANOTROPY, HUMAN (1333)
 CARCINOMA, HORMONES, ANTIGENICITY (1740)
 CHRONIC THYROIDITIS, RAT, TRYPAN BLUE (0034)
 CORRELATION, LIVER, ALPHA-FETOPROTEIN (0231)
 7,12-DIMETHYLBENZ(A)ANTHRACENE, 3-METHYLCHOLANTHRENE, RAT, MOUSE (0436)
 DISTRIBUTION, HODGKIN'S DISEASE (1218)
 FIRST PREGNANCY, MAMMARY CARCINOMA, WEIGHT (1618)
- HODGKIN'S DISEASE, HISTOLOGY, TWO ENTITIES (0260)
 INOCULATION, MOUSE MAMMARY TUMOR VIRUS, MILK ANTIGEN ASSAY (0194)
 NEW ZEALAND MICE, MURINE SARCOMA VIRUS, TUMOR REGRESSION (1932)
 PERINATAL PERIOD, TUMOR PROFILE, URETHAN INDUCTION (0496)
 TEEN-AGE PATIENTS, CYTOLOGIC ATYPIA, CARCINOMA OF THE CERVIX (0744)
 TUMOR, EPIDEMIOLOGY, REVIEW (1725)
 TUMOR SPECTRUM, URETHAN (0492)
 TUMORIGENICITY OF MOUSE CELL LINES, IN VITRO NEOPLASTIC TRANSFORMATION (1229)
 URETHAN, TUMOR INDUCTION, HAMSTERS 1361
 VARIATION, RH NEGATIVITY, LEUKEMIA (0801)
 WOMEN, SURVIVAL RATE, MAMMARY CARCINOMA (0287)
- AGGLUTINATION
 TRANSFORMED CELLS, SIMIAN VIRUS 40, ADENOVIRUS TYPE 12, ORNITHINE, LEUCINE POLYMER (0661)
- AIR POLLUTION
 BRONCHOGENIC CARINOMA, EPIDEMIOLOGY, CZECHOSLOVAKIA (0768)*
 CARCINOGENS, BRONCHIAL CARCINOMA, HYDROCARBONS (0461)
 EPIDEMIOLOGY, LUNG CANCER (0016)
 LUNG CANCER, SMOKING, ITALY (0383)*
 LUNG CANCER MORTALITY, AUSTRALIAN IMMIGRANTS (2049)
 URBAN, CARCINOMA OF THE TONSIL, CANINE RESPIRATORY TRACT CARCINOMA (1183)
- ALDRIN
 TUMORIGENICITY, DIELDRIN, ENDRIN (0421)
- N-ALKYL-4-AMINOAZOBENZENE
 AZO DYE BINDING (0056)
- ALKYLATING AGENT
 CHLORAMBUCIL, BUSULPHAN, BONE MARROW CELL PROLIFERATION (2070)
 CYCLOPHOSPHAMIDE, CARCINOGENICITY, RAT, MOUSE (0906)
 N-DIAZOACETYLGLYCINAMIDE, N-DIAZOACETYLGLYCINE HYDRAZIDE, CARCINOGENICITY, MOUSE (0401)
 DNA, REPAIR SYNTHESIS, HELA, HAMSTER (2254)
 DNA, RNA, REPAIR, HELA (2248)
 1,3-PROPANE SULTONE, 1,4-BUTANE SULTONE, RATS, NEUROGENIC TUMORS (0905)
 THYMUS, DNA, THERMAL DENATURATION, CALF (0422)
 TRENIMON, MUTAGENESIS, HAMSTERS, BONE MARROW (0903)
- ALUMINUM
 4-NITROQUINOLINE 1-OXIDE, LUNG ADENOCARCINOMA (0096)
- AMELOBLASTOMA
 DENTAL CYST, JAW (0244)
 ODONTOGENIC TUMORS, ENZYME ACTIVITY (0784)

INOACETONITRILE
 METABOLISM, DIMETHYLNITROSAMINE
 (0961)
 NO ACID
 ACCEPTOR RNA, AVIAN MYELOBLASTOSIS
 VIRUS, AMINOACYLATION CAPACITY
 (0585)
 ALPHA-AMINOISOBUTYRIC ACID UPTAKE,
 IRRADIATED RAT LIVER (1386)
 ARGININE DEPRIVATION, POLYOMA
 VIRUS, INFECTION (1112)
 COMPOSITION, T-ANTIGEN, ADENOVIRUS
 TYPE 12, HAMSTER (1526)
 LEUKEMIC LYMPHOBLASTS, TRANSFER RNA
 (0790)
 LEUKOSIS, ANTIGEN, VIRUS (1027)
 NOAZOBENZENE
 N,N-DIMETHYL-4-AMINOAZOBENZENE,
 LIVER CELL NUCLEI RNA POLYMERASE,
 OTHER DERIVATIVES, RAT (1783)
 NOAZOTOLUENE
 ORTHO-, NUCLEIC ACID BINDING, PROTEIN
 BINDING (0028)
 AMINO-2',3-DIMETHYL-AZOBENZENE
 BINDING, LIVER PROTEIN, RAT (0432)
 TA-AMINOISOBUTYRIC ACID
 BLADDER CARCINOMAS (0336)*
 NOSTILBENE
 DERIVATIVES, EAR DUCT TUMOR, TRANS-4-
 DIMETHYLAMINOSTILBENE (0031)
 BONE MARROW, THYMUS, MITOSIS, RAT
 (0818)
 CELL SURFACE ALTERATIONS, ROUS
 VIRUS, POLYOMA VIRUS (1079)
 EMIA
 GASTRIC CARCINOMA, VITILIGO (0777)
 ILINE
 LIPID HYPERPLASIA, RAT ADRENAL CORTEX
 (0925)
 RAT CORPORA LUTEA, STEROIDOGENESIS
 (1319)
 TIBIOTIC
 BIOMYCIN, ORTHOAMINOAZOTOLUENE, LIVER,
 MOUSE (0025)
 EXORIBONUCLEASE, RNA, EHRLICH'S
 ASCITES TUMOR (2179)
 TIBODY
 ANTILYMPHOCYTE SERUM, LYMPHO-
 CYTES, SARCOMA, MICE (2442)
 ANTILYMPHOCYTE SERUM, SPON-
 TANEOUS LYMPHOMA, MOUSE
 (2431)
 ANTISARCOMA, HUMAN SARCOMA, VIRUS
 (1880)
 ANTISARCOMA, IMMUNITY, SKELETAL
 SARCOMAS (0710)
 4-AZOGUINOLINE-1-OXIDE,
 4-NITROQUINOLINE-1-OXIDE (1994)
 COMPLEMENT, EHRLICH'S ASCITES
 TUMOR, NORMAL HUMAN SERUM
 (2417)
 EPSTEIN-BARR VIRUS (0757)
 EPSTEIN-BARR VIRUS, BURKITT'S
 LYMPHOMA (1973)
 EPSTEIN-BARR VIRUS, BURKITT'S
 LYMPHOMA, TAIWAN MONKEY (1972)
 EPSTEIN-BARR VIRUS, CHILDREN (0758)

FELINE LEUKEMIA VIRUS, VIRAL ANTIGEN
 (0163)
 GROSS LEUKEMIA VIRUS, GLOMERULO-
 NEPHRITIS, MOUSE (1034)
 GROSS LEUKEMIA VIRUS, IMMUNO-
 FLUORESCENT FOCUS ASSAY (1036)
 HEMAGGLUTINATION, INFECTIVITY, RAT
 VIRUSES (0559)
 HERPES SIMPLEX VIRUS,
 PERSISTENCE, EARLE'S L CELLS,

 ROUS SARCOMA, ANTI-LYMPHOCYTE SERUM, QUAIL (2446)
 ROUS SARCOMA, ASCITIC SARCOMA, NUCLEIC ACID, MOUSE CELL (1080)
 ROUS SARCOMA, AVIAN LEUKOSIS, CHICK EMBRYO CELL CULTURE, DNA SYNTHESIS (0566)
 ROUS SARCOMA, AVIAN LEUKOSIS IN PIGEONS, COMPLEMENT FIXING ANTIGEN (1966)
 ROUS SARCOMA, AVIAN MYELOBLASTOSIS, DNA POLYMERASE (1081)
 ROUS SARCOMA, LACTERIA (1946)
 ROUS SARCOMA, CELL SURFACE GLYCOPROTEINS (1939)
 ROUS SARCOMA, CHICK EMBRYO, CONTACT
 ROUS SARCOMA, RNA SYNTHESIS, BROMO-DEOXYURIDINE (0645)
 ROUS SARCOMA, ROUS ASSOCIATED, VIRION CORE ANALYSIS (0206)
 ROUS SARCOMA, SARCOMA VOLE (0642)
 ROUS SARCOMA, 7S VIRAL RNA (1088)
 ROUS SARCOMA, SONIC DISRUPTION, OVERGROWTH STIMULATING ACTIVITY (0644)
 ROUS SARCOMA, TRANSFORMED HAMSTER CELLS, VIRAL GENOME (1486)
 ROUS SARCOMA, TRANSFORMED STATE, TEMPERATURE SENSITIVE MUTANT (0205)

ROUS SARCOMA, TRANSFORMATION,
 REVERSION, HAMSTER CELLS (2361)
 ROUS SARCOMA, TUMOR RECURRENCE (0650)
 ROUS SARCOMA, TUMOR SPECIFIC ANTIGEN,
 MOUSE (0653)
 ROUS SARCOMA, ULTRASTRUCTURE OF CANINE
 GLIOMAS (1484)
 ROUS SARCOMA, URIDINE METABOLISM,
 CHICK CHORIOALLANTOIC MEMBRANE
 (0643)
 ROUS SARCOMA, UV ACTIVATION, HELPER
 (1479)
 ROUS SARCOMA, VARIANT STRAIN,
 TUMORIGENICITY FOR MAMMALS (1087)
 ROUS SARCOMA, VESICULAR STOMATITIS,
 SMALLPOX VACCINE (0560)
 ROUS SARCOMA, VIRUS-SPECIFIC RNA
 (1487)
 ROUS SARCOMA MUTANT, FUSIFORM CELL
 TRANSFORMATION (0649)
 ROUS SARCOMA TYPE 0, DILUTION,
 PROGENY, QUAIL (2366)
 ROUS SARCOMA VIRUS COAT ANTIGEN,
 HETEROKARYOTIC CELLS, VIROGENIC CELL
 FUSION (0201)
 ROWSON-PARR, INDUCTION OF LYMPHOMA,
 MICE (0610)
 SARCOMA, ANTIBODY, HUMAN (0147)
 SARCOMA, LEUKEMIA, TRANSFORMATION,
 MOUSE, RAT (2350)
 SARCOMA-LEUKEMIA VIRUS, VIRAL RNA-DNA
 HYBRID MOLECULE, DNA POLYMERASE
 TEMPLATE (0143)
 SARCOMA 180, ANTIGEN (1995)
 SCHMIDT-RUPPIN ROUS, SARCOMA, THYMUS,
 CHICKEN (0656)
 SENDAI, HAMSTER, CHICK EMBRYO, M-RNA
 (0207)
 SHOPE, VX7 TYPE CARCINOMA, PAPILLOMAS,
 NUCLEIC ACID (1074)
 SHOPE FIBROMA, COWPOX, CELLULAR DNA
 SYNTHESIS, INHIBITION (2380)
 SHOPE FIBROMA, CYTOCIDAL VIRUS, RABBIT
 (2379)
 SHOPE FIBROMA, DNA, RK 13, LACK OF
 HOMOLOGY (1949)
 SHOPE FIBROMA, FOCUS FORMATION,
 NUCLEIC ACID SYNTHESIS (0657)
 SHOPE PAPILLOMA, ANTIGENICITY (0658)
 SHOPE PAPILLOMA, ENZYME, RABBIT (2381)
 SHOPE PAPILLOMA, EPIDERMAL PAPILLOMAS
 (1522)
 SIMIAN ADENOVIRUS, DNA, DENSITY (2296)
 SIMIAN ADENOVIRUS 7, 7,12-DIMETHYL-
 BENZO(A)ANTHRACENE, TUMOR TRANSPLANT
 IMMUNITY (1982)
 SIMIAN ADENOVIRUS 7, HAMSTER CELLS
 (2324)
 SIMIAN ADENOVIRUS 7, PROPERTIES OF
 VIRUS POPULATION (1457)
 SKIN-HETEROGENIZING, SARCOMA K-237,
 MICE (0144)
 SKIN HETEROGENIZING, STRAIN SPECIFIC
 VIRUS, GENETIC TRAIT (0145)
 SMALLPOX VACCINATION, FIBROSARCOMA
 (1416)
 SNYDER-THEILEN FELINE SARCOMA, FILTER-
 ABLE AGENT, HUMAN CELL CULTURES (1073)

SPECIES-SPECIFIC VIRUS, POLIOVIRUS,
 SV40, ADENOVIRUS, POLYOMA (1507)
 SV40, ADENOVIRUS 2, HYBRID, VIRAL DNA
 (2332)
